**HORTICULTURIST** (with qualifications equivalent to a pass degree or the Royal Horticultural Society's final diploma, and an interest in applied entomology and in other topics relating to crop pests) in THE DEPARTMENT OF AGRICULTURAL AND FOREST ZOOLOGY, to manage the plots and experiments at the Pen-y-fnidd Field Station, Bangor—Mr. J. Hobart, Department of Agricultural and Forest Zoology, University College of North Wales, Bangor, North Wales (September 3).

**SENIOR LECTURER** (with a Ph.D. in physics, or equivalent in research publications, and some university teaching experience) in PHYSICS at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (September 3).

**SENIOR LECTURERS (2); and LECTURERS/ASSISTANT LECTURERS** (with at least a good honours degree with suitable teaching and research experience) in THE DEPARTMENT OF MATHEMATICS, University of Malaya—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Kuala Lumpur and London, September 6).

**ASSISTANT LECTURER** in THE DEPARTMENT OF MEDICAL PHYSICS—The Secretary, Royal Free Hospital School of Medicine (University of London), Hunter Street, London, W.O.1 (September 7).

**POST-DOCTORAL RESEARCH ASSISTANT** in THE DEPARTMENT OF CHEMISTRY for investigations concerning the synthesis and study of organometallic compounds containing fluorocarbon groups, in collaboration with Dr. R. D. Chambers—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (September 10).

**SENIOR LECTURER/LECTURER in NUMERICAL MATHEMATICS; and a PROGRAMMER in THE COMPUTING CENTRE**, University of New England, Armidale, New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 10).

**RESEARCH SCIENTIST or SENIOR RESEARCH SCIENTIST** (biochemist, with a Ph.D. degree or postgraduate experience of equivalent standard and duration supported by satisfactory evidence of research ability, and preferably previous

experience in the field of fungal biochemistry) in THE BIOCHEMISTRY SECTION of the Division of Plant Industry, Commonwealth Scientific and Industrial Research Organization, Canberra, A.C.T., Australia, to initiate studies on the biochemistry of spore germination with particular reference to *Peronospora tabacina* (Blue Mould) in tobacco—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.O.2, quoting Appointment No. 180/723 (September 11).

**LECTURER in VETERINARY PHYSIOLOGY**—The Secretary, Trinity College (University of Dublin), Dublin, Republic of Ireland (September 18).

**LECTURER/SENIOR LECTURER in AERONAUTICAL ENGINEERING** at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 15).

**LECTURER in CYBERNETICS** in THE DEPARTMENT OF APPLIED PHYSICAL SCIENCES—The Registrar, Room 22 (O.R.B.), The University, Reading (September 18).

**LECTURERS (2) in GEOGRAPHY** at the University of Canterbury, Christchurch, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, September 24).

**LECTURER in THE DEPARTMENT OF PSYCHOLOGY**, University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 25).

**LECTURER/SENIOR LECTURER** (preferably specialist in the fields of chemical or process metallurgy) in METALLURGY at the University of Newcastle, New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 30).

**RESEARCH ASSISTANT** (with a degree in zoology or in forestry, and preferably previous experience in research involving field studies) to work with the Lecturer in Forest Zoology on investigations into the ecology and biological control of foreign insects—The Secretary, The University, Aberdeen (September 30).

**CHAIR of GEOGRAPHY** at the University of Otago, Dunedin, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 15).

**CHAIR of GENETICS**—The Registrar, University College of Swansea, Singleton Park, Swansea (October 30).

**SCIENTIFIC OFFICER** (preferably specialising in biochemistry, animal genetics or invertebrate zoology)—The Director, Tropical Fish Culture Research Institute, Batu Berendam, Malacca, Malaysia (October 31).

**AGRICULTURAL CHEMIST** (national of the United Kingdom or the Republic of Ireland, with an honours degree in chemistry and a reasonable amount of experience) in MALAWI, to organize and control a fairly large chemical laboratory working on various problems connected with the development of agriculture—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RO 213/134/66.

**CHEMIST** (with a pass degree or equivalent qualification, and preferably previous experience in handling radioisotopes) for interesting work on the preparation of short-lived radioisotopes from the cyclotron—The Director, Medical Research Council Cyclotron Unit, Hammermith Hospital, Du Cane Road, London, W.12.

**BIOPHYSICIAN SPECIALIST** (with experience of transistor techniques) in THE DEPARTMENT OF VETERINARY PHYSIOLOGY, to take charge of the Electronic Workshop—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh.

**GRADUATE RESEARCH ASSISTANT** (preferably with experience in the field of tissue culture) to work in an organ culture laboratory—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

**LECTURER or ASSISTANT LECTURER or (exceptionally) SENIOR LECTURER in MATHEMATICS**—The Assistant Registrar (Establishment), University of Sussex, Stanmer House, Stanmer, Brighton, Sussex.

**LECTURER or ASSISTANT LECTURER** (preferably with research interests in forensic chemistry, toxicology or enzymology) in CHEMISTRY—The Secretary, The Royal Veterinary College (University of London), Royal College Street, London, N.W.1.

**RESEARCH ASSISTANT in THE DEPARTMENT OF CHEMISTRY AND BIOLOGY**, to assist in research on the nutritional aspects of smoking—The Secretary, Welsh College of Advanced Technology, Cathays Park, Cardiff.

**RESEARCH ASSISTANT** (with a diploma in technology, a degree or their equivalent) in THE PHYSICS DEPARTMENT, to work on magnetic and related properties of materials over a wide range of temperatures—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref. 33/AF.

**RESEARCH ASSISTANT** (with a good honours degree in animal physiology or zoology or an equivalent qualification, and preferably an interest in biochemistry) in THE PHYSIOLOGY DEPARTMENT, for an investigation of blood levels of oxytocin in relation to reproduction and lactation—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, Berkshire, quoting Ref. 64/N/16.

**RESEARCH ASSISTANT** (with a good honours degree in psychology) in THE DEPARTMENT OF PSYCHOLOGY for an investigation of associative aspects of human verbal learning—The Deputy Secretary, The University, Southampton.

**RESEARCH ASSISTANT** (with qualifications in physics or chemistry) in THE DEPARTMENT OF CHEMISTRY, to work on dielectrics with Dr. Mansel Davies—The Registrar, University College of Wales, Aberystwyth.

**RESEARCH LECTURER in CLINICAL PSYCHOPHARMACOLOGY**—The Secretary, Trinity College (University of Dublin), Dublin, Republic of Ireland.

**SENIOR II TECHNICIAN** (preferably with experience in bacteriology and haematology)—The Secretary, Birmingham and Midland Eye Hospital, Church Street, Birmingham, 3.

**TUTORIAL RESEARCH STUDENT** (man or woman) in BOTANY—The Secretary, Royal Holloway College (University of London), Englefield Green, Surrey.

## REPORTS and other PUBLICATIONS

Great Britain and Ireland

Cement and Concrete Association. Report for the year 1964. Pp 116. Annotated Bibliography on the Creep and Shrinkage of Concrete. Pp 70. (Publication Ch. 47.) 20s. (London: Cement and Concrete Association, 1965.)

Bulletin of the British Museum (Natural History). Geology. Vol. 10, No. 5: Fossil Gnathopods from the Trias Fium, Santa Cruz Province, Argentina. By Sergio Arochagasky. Pp. 119-137+5 plates. 28s. Zoology. Vol. 12, No. 7: A Review of the Hoploid and Clupeoid Fishes of the Red

- Sea and Adjacent Regions. By P. J. P. Whitehead. Pp. 225-281. 10s. (London: British Museum (Natural History), 1965.) [236]

## ROAD, RAIL AND WATER TRANSPORT

THE debate in the House of Lords on urban planning and development, opened by Lord Llewelyn-Davies on May 19, was notable for the authority of the speeches, particularly those of Lord Llewelyn-Davies and Lord Holford; Lord Mitchison replied on behalf of the Government. Lord Llewelyn-Davies spoke as chairman of a committee advising the Minister of Housing and Local Government on research in urban planning and also as a member of a similar committee advising the Minister for Land and Natural Resources. Among other things, he referred to the work which Lord Holford, as technical adviser in the Ministry, had done to build up theoretical structures on which the whole practice of British planning now rests.

He began by pointing out that the subject was urgent principally because of the great increase in population, the almost equally large increase in the use of the motor-car, and the fact that such a high proportion of houses and other buildings were now due for renewal. It was essential that we should attempt to guess at what life should be like in the future and design for it. Even better, we should attempt to imagine or to envisage a pattern of urban development and city construction sufficiently flexible to absorb and to ride with the changes in the pattern of human life and living which would occur within the life of the buildings which we propose to erect.

Lord Llewelyn-Davies urged that decisions as to planning were not matters for technologists, planners or architects: they were matters for the elected representatives of the people who should, however, take the decisions on the information and advice which could be supplied, although they were ultimately political issues. The concepts of planning were concerned with the limitation of the size of cities by establishing green belts and deliberately restricting development; with providing for increased population, so far as possible in self-contained, fairly small new towns some distance away from existing centres; and with the control of development within the cities in accordance with a plan for the use of land. He urged that an important criterion of effective planning should be that wise choices were made possible for the life of the institutions, such as universities and hospitals, which served the great cities. He did not believe that we needed to suffer the desolation of important and valuable areas of countryside to meet the demand of increasing population; there was enough space, but organization was needed to ensure that the buildings were put in the right and not the wrong place. He believed that a solution of the problem of urban planning and development was only possible by a massive direction of our universities towards research into the social, economic and architectural problems of urban affairs. He referred especially to Lord Silkin's advocacy of the establishment of an architectural research council for the built environments—this has since been supported by the Royal Institute of British Architects and other bodies, and by Lord Holford.

Lord Llewelyn-Davies spoke, of course, some weeks before the report of the Heyworth Committee was published (*Nature*, 207, 559; 1965) and before the Government had announced its acceptance of the recommendation to establish a Social Science Research Council, with which the proposal for a research council for the built environment is closely related. Lord Holford himself, in a maiden speech, began by expressing regret that we

separated development and preservation and did not consider preservation of historic and other buildings or urban open spaces as an integral part of development and not an opposing thing. He pointed out, moreover, that we seemed no longer to anticipate change and move to meet it, but merely to struggle to keep up with changes that had already overtaken us. We could only prepare for change by setting the stage for industrial building of various kinds; however, such planning could make all the difference to the quality of the environment and to its sensible distribution, and he added that the quality of our urban environment depended very largely on our attitude towards preservation. A preservation policy was important because the more imaginative and more modern architects in Britain, and especially landscape architects, were just as keen on keeping the creative work of the past under economic conditions as were those concerned solely with preservation. Problems of new accommodation could not be solved merely by rehabilitation and preservation of old buildings; however, we could minimize our loss by using these buildings in imaginative ways.

Preservation was also needed on the regional scale, and the need was for three things: first, for some financial help for local authorities, particularly in regions which were severely damaged during the Second World War, and where the rates were inadequate to carry all the social burdens; secondly, for an intelligent sub-regional plan; thirdly, for trained advice (which was very scarce)—advice which was independent and objective, independent not only of the developers but also of the local authority who might be a little too zealous in making clearance areas throughout the controlled district. He supported Lord Llewelyn-Davies in urging that the Ministry should have disinterested technical assessors to give some stature and substance to the decisions which it had to make in such large numbers. He urged that we should begin to think on all these problems: the giving of advice on development plans; the making of schemes within development plans; the combination of preservation and development on a basis which, of necessity, went beyond the boundaries of individual local authorities.

Lord Esher, who followed, strongly supported Lord Llewelyn-Davies on the overriding need for research and, like Lord Holford, referred to the report from the Royal Institute of British Architects. This report had pointed out that 58 of the chief officers in charge of planning in 109 county boroughs had no planning qualifications, while 449 out of 531 in the second-tier authorities were without such qualifications. Of staff working on planning in local authorities fewer than half had any planning qualifications and only 4 per cent were architects. So far as this arose from a shortage of qualified people, the professional institutions were doing all that they could to remedy the situation, but this took time. There also seemed to be a shortage of demand, and planning consultants were not being fully used; our available resources were not either fully or effectively deployed. He suggested that the Minister should remove delegated planning powers from authorities who did not possess qualified planning staff.

The Earl of Gosford, who followed, referred particularly to the transport aspect, quoting Lord Hastings's emphasis that the Buchanan Report provided a framework within which a programme of urban redevelopment could proceed. We could not expect to do everything at once and

our resources were already fully committed for the next few years, but the Earl of Gosford thought that the recent statements of the present Minister of Transport suggested that less and less was to be expended on the problem of roads, both outside the cities and, particularly, on roads inside the cities. He thought the urban programme was the key to urban renewal, in the context both of quality and progress. If our towns were not renewed in a context of planning which accepted the motor-car, there was a real danger that their prosperity would diminish. Lord Arwyn also strongly supported the suggestion for massive research at universities, and particularly for effective liaison between the universities, the professions and the building industry. Lord Hastings, however, was doubtful whether we should, as Lord Llewelyn-Davies had suggested, try to base our cities on institutions than on houses and people in houses. He thought we must try to work out as soon as possible a technique for redeveloping town centres, and that we must recognize that human considerations and economic planning were equally important. Lord Mitchison, replying for the Government, said that with scientific developments and other changes, town and country planning should be as flexible as one could possibly make it. It was not, however, merely a matter of science or population, but also of the kind of life people might wish to live in twenty or thirty years time, when their values also might have changed greatly. He agreed with what the Minister of Transport had said on April 14, that the only satisfactory basis on which local authorities could develop their plans with the necessary degree of financial realism would be on the assumption that the future scale of investment in urban road construction was unlikely to be very different from that programmed and already announced for the period up to 1970. While agreeing with earlier speakers as to the importance of land planning, he thought that we could only obtain the kind of planning we desired with the help of an authority specifically set up to see that land was put to the right use when development took place. As regards organization, he said that the Minister would look at the machinery of planning through a planning advisory group and that the report of this group would shortly be issued. A Directorate of Urban Planning had been set up under the Minister's technical adviser on urban planning. This body would consist partly of administrative and partly of professional people and was intended to lead a new drive into town planning and design, and to advise on what could be done on such questions as using the very limited amount of skilled manpower now available. He welcomed the report from the Royal Institute of British Architects on manpower, and said that the Government had already asked the University Grants Committee to consider the best ways and means of stimulating a greater output of trained planners both in the short term and in the long term. Local government finance, and central finance, were also being thoroughly investigated, including questions of rates and of shifting some of the burden from the rates to central finance.

The development not only of roads but also of waterways and of the major railway trunk routes should be considered with a hard-headed approach; and if we could, within five years, build up a national fleet of 450 pairs of narrow boats carrying a million tons a year we would remove 100,000 lorry loads from the roads. Quite apart from the amenity aspect, this possibility seems to be worth serious examination. The study of canal transport

now being prepared for the Inland Waterways Association should be carefully studied by Ministers, as well as by British Waterways. Lord Hinton, who is investigating the co-ordination of national transport, has before him now a three-stage programme for a modern waterway system for Britain, which was submitted by the Association early in August. Even at the present moment the £170 million could well be a most profitable investment.

The recent Beeching Report issued in February (British Railways Board. Pp. 100. 15s.) provides a critical examination of the trunk railway routes with the idea of selecting routes for future intensive use, but not selecting lines for closure. The report was made to enable the selection of trunk routes to be subjected to constructive criticism, to permit good planning of the next phase of development expenditure, and to enable any future proposals for closure of trunk lines or decrease in the utilization of lines to be seen in a broader context, while permitting the proper development of commercial policies, and giving customers a clearer view of the future. It thus complements the report on *The Reshaping of British Railways*, published in March 1963 (*Nature*, 198, 1233; 1963), and develops further the constructive proposals of that report which have largely been ignored in public discussions. Essentially these discussions have been centred on the proposed abandonment of the parts of Britain's railway system deemed 'unsound'. Like the earlier report, it is concerned with the economic aspect, stressing that the level of annual expenditure on through-route maintenance, renewal and improvement is likely to continue at the present level of about £85 million per annum for many years if the whole through-route system is maintained. Substantially lower expenditure on suitably selected routes is estimated as likely to provide all the capacity required to meet foreseeable future demand. It is thus open to the criticism that it is concerned almost solely with the economic facts, and also that the position of the railways with respect to other forms of travel is not considered. Like the debate in the House of Lords already noted, the Report refers to reports already issued, such as *The South-East Study, 1961-1981*, dealing with the growth and distribution of population and industry in the South-East region, issued in 1964, and it refers also to the Hall Report on *The Transport Needs of Great Britain in the Next Twenty Years* published in 1963. Considering the changes in the economy which are likely to affect transport over the next twenty years, the Report expects an increase in population from 54.2 millions to 62.5 millions: its proposals are based on the assumption of rates of growth of 3 and of 4 per cent. Two important assumptions are made on the distribution of population and industry. The rate of growth of the former is assumed to be comparatively even throughout Britain with no major redistribution and, although some change is foreseen in the commodity pattern of production, it is assumed that the geographical spread of general industrial activity would remain the same and that growth would also be uniform. These assumptions may not pass unchallenged. However, the further assumptions as to the pattern of transport demand between the main centres in 1984 are likely to be accepted generally; for example, that the total internal consumption of coal will remain fairly steady over the next 24 years (if anything, it is more likely to decline than increase), and that steel production will grow at a lower rate than the average for all industries, rising to some 40 million tons by 1984. It is estimated that some 19 million tons per annum of the existing freight traffic

could be transferred from roads to liner-train services as they build up, but for passenger traffic the assumptions and forecasts are much more questionable. It is taken for granted that public services on trunk lines will decline, and consideration of passenger traffic is limited to inter-city passenger movements. Nevertheless, the assumption that, in the main, passenger traffic will increasingly go by road in private cars ignores entirely the desirability of doing everything possible to take even private car traffic off the roads, at least in certain areas, and ignores other considerations entirely, such as were powerfully argued by Mr. C. D. Foster in *The Transport Problem*, in 1963, and more recently by Mr. R. Calvert in *The Future of Britain's Railways*\*.

The conclusions of the second Beeching Report are that the cost of providing the railway track and signalling per unit of traffic passing over it should be reduced to a level which enables services to be provided on a competitive basis. If such changes were made, the railways would be able to increase their freight carrying and the overall demand for rail transport on the trunk routes would appreciably increase over the next twenty years. The present network of through-routes is under-utilized, but if advantage is taken of technological progress in signalling and movement the disparity between capacity and use will increase. The through-movement could be channelled through a reduced network of lines amounting to some 3,000 route miles instead of the 7,500 miles provided to-day, and this would reduce route costs to about half their present level. If the railways concentrate on cheap bulk movement their prospects as trunk carriers can be revived. The real choice, Dr. Beeching argues, is between an excessive and increasingly uneconomic system with a corresponding tendency to fall into disrepute and decay, or the selective development and intensive utilization of a more limited trunk-route system.

It is claimed that the study provides a basis for positive planning and that it should be possible to concentrate railway investment on the selected trunk routes in the confidence that here the essential dense flows of traffic will be maintained. Even if that claim is conceded, the second Report is too pessimistic and even defeatist. It ignores, except for goods traffic, the overriding need to take off the roads, even from the point of view of safety, as much traffic as is reasonably possible. It fails to recognize that much passenger traffic is on the roads simply because of the failure of the railways to offer attractive transport for passengers in the mid-twentieth century. The Report does not consider rail and road and even waterway traffic as complementary; it fails completely, except perhaps for the liner trains, to consider the railways in terms of what they could be. An obsession with long-distance and bulk traffic leads in both Reports to the possibilities of the Diesel rail bus and new operating methods for local and intermediate traffic being disregarded.

For all these reasons, Dr. Beeching's reports should be read in the light of such a book as that by Mr. Calvert. Mr. Calvert's imaginative, but constructive, look at the inherent possibilities of modernization provides the essential corrective and relates railways to the wider and more general problem of planning development in which roads and waterways as well as railways have their place. He looks, also, at the implications of the Channel Tunnel and at the rationalization of operating methods as well as at modernization. Much of his book is technical, but the

broad issues are plain enough and no reader is left in doubt as to the very real asset which the railways still represent. Wisely and imaginatively used, they could make a vital contribution not merely to easing congestion and danger and waste on the roads, but also to safeguarding the erosion of the countryside and to restoring a standard of living in which man can regain some of the control over his environment that he has at present lost. There is evidence in the House of Lords debate that the possibilities and the opportunities are already being recognized.

## AN INTRODUCTION TO NUCLEAR STRUCTURE PHYSICS

### Nuclear Physics

An Introduction. By W. E. Burcham. Pp. xiv+739. (London: Longmans, Green and Co. Ltd., 1963.) 70s.

PROF. BURCHAM'S *Nuclear Physics: an Introduction* is a good book, carefully and thoughtfully written, that does, admirably, the job it sets out to do. It is a teaching book, a text-book; it does not pretend to take the reader to the growing points of nuclear physics or to infect him with the excitement of research. I wish it had, both because I think that every teaching book should be open-ended and give major glimpses of the next stage of the game and what it is all about, and also because I know that Prof. Burcham could have done this very well; but he has done a considerable service: he has provided us with the first really good undergraduate text in nuclear physics available in English. This is a strong statement, but it is true. Until this book came along there was no single undergraduate text that could be recommended with confidence as being not positively misleading. I believe that Prof. Burcham's text is still a little unbalanced: in my view it contains too much about detectors, accelerators and classical radioactivity and not enough about nuclear models, symmetry properties and reactions. But this is a personal point of view, and the present book is very much better in its balance than any of its predecessors. There is one very important matter, however, that must be mentioned here, though not as a criticism. It is that Prof. Burcham's text is about nuclear structure physics. The great excitements of the sub-atomic world are now sub-nuclear rather than nuclear, in the field of what we used to call elementary particles but which we now recognize as entities much more essentially complex than the nucleus itself. This world of high-energy physics is not treated in Prof. Burcham's text, but it must be an important part of any teaching course in nuclear physics that, on the nuclear structure side, attains the level of this book. Nuclear physics has its two sides, nuclear structure and high energy, and a properly-constructed course must contain both. High-energy physics is at an earlier stage of its development than nuclear structure physics and does not yet lend itself to the consolidated type of treatment of Prof. Burcham's text, but many basic features are nevertheless well established and must be taught at the undergraduate level because of the enormous intellectual importance of the subject. This, then, is a warning rather than a criticism.

Prof. Burcham's treatment of his subject is at the undergraduate level but probably contains more detail than will be accommodated in most 'finals' syllabuses. It is not a suitable graduate text because it does not look outwards to the unsolved problems and is too elementary in its approach, but it could still be useful as a bridge between the undergraduate course and research; many of its references are to research and graduate-type works. The book's use of references is excellent and enables a picture to be built up of how the subject developed; it is part of Prof. Burcham's approach which rather

\* *The Future of Britain's Railways*. By Roger Calvert. Pp. 176+16 plates. (London: George Allen and Unwin, Ltd., 1965.) 35s. net.

successfully combines the historical and the logical methods.

A considerable portion of the book is devoted to matters that are not properly nuclear physics: 48 pages to the spectroscopy of atoms and molecules, 69 pages to properties of ionising radiations, 53 pages to instruments, 43 pages to the measurement of radiation, and 59 pages to accelerators. All this is important if you want to know how it comes about that we know what we do about the nucleus, but of no interest if we simply want to understand the nucleus. As Prof. Burcham emphasizes, his is an "experimentally-oriented" book. My own view is that it is more important to teach undergraduates what we know about the nucleus itself than about the devices, apparatus and techniques by which that knowledge is obtained, but again this is a matter of opinion. At least Prof. Burcham distinguishes clearly between the wood and the trees and does not attempt to give the impression that the passage of electrons through thick absorbers has something to do with the physics of the nucleus.

Although Prof. Burcham's approach is experimental it is far from purely descriptive. He is quite free in his use of formulae and analysis and, although he works out nothing in detail, he gives the bare bones of the steps by which the theoretical results are achieved. He also attaches, wherever he can, a physical interpretation to the formal quantum mechanical result—for example, in explaining that the ortho-helium levels lie lower than the corresponding para-helium levels because the spatially anti-symmetric ortho-helium states inhibit the close approach of the two electrons that corresponds to large Coulomb energies whereas the spatially-symmetric para-helium states allow such close approach.

There are lacunae—for example, Prof. Burcham misses a good opportunity of showing how simple and general some aspects of nuclear behaviour are by omitting all mention of the photo-nuclear giant resonance, perhaps the only piece of nuclear dynamics obviously common to all nuclei and which is simply a child on a swing. But in bringing together the various aspects of nuclear behaviour, putting into them as much physical content as possible and making them assimilable at the undergraduate level (forgetting his occasional oracular remark such as "This is a result of quantum field theory"), Prof. Burcham has done an excellent and commendable job; we thank him for it.

D. H. WILKINSON

## IN DEFENCE OF METAPHYSICS

### *Is Metaphysics Possible?*

By Pratima Bowes. Pp. 237. (London: Victor Gollancz, Ltd., 1965.) 42s. net.

### *The Foundations of Metaphysics In Science*

By Errol E. Harris. (Muirhead Library of Philosophy.) Pp. 512. (London: George Allen and Unwin Ltd., 1965.) 68s.

THESE two books are very different in character as well as in scope: at the same time, however, they display certain aspects of knowledge which make them more valuable together than separately. Both contain traces of apologetics, which indeed are almost inescapable in the present state of the philosophical climate. The reader will try to discover what the bridge is which spans the gap between any metaphysical system (if such exists) and science. Clearly, this is entropy, a concept which becomes more and more significant as the authors' themes develop. Why this should be so will appear in the sequel; for the moment we see biophysics and its partners literally 'daring' entropy to increase as a matter of course. Epistemologically, perhaps this is the greatest break-through of synoptic thinking, even if there are many limitations and question marks. Nevertheless, in general, the second law of thermodynamics is still in command.

Mrs. Pratima Bowes's *Is Metaphysics Possible?* is distinguished by a becoming humility, accompanied by a conviction from the start that the answer to her own question is 'yes'. Prof. Acton, in a most readable introduction, puts his finger on a major point by remarking that logical positivism has flourished by the negative policy of denying meaning to transcendental metaphysics because empirical verification is lacking. Mrs. Bowes goes further, and pins down this antipathy to a dislike of mystery. Such matters—so the argument runs—are not genuine, and their discussion is pointless. One may well agree that all this is a little too easy: for example, the wildly improbable states (as judged statistically) that come not only into existence, but also into continued existence, in the biological sciences, are thoroughly mysterious. There is, as yet, no down-to-earth reason for such occurrences. One day there may be, but meanwhile some discipline akin to metaphysics (which never presumes to unearth anything) may so keep active minds intent on broad issues—without neglecting details when relevant—as actually to hasten discovery.

Metaphysics emerges as individual rather than collective, an art rather than a science; in this it resembles aesthetics, and tends to stand on the touch-line in preference to becoming involved in the rough and tumble of ordinary life. In a word, all this is not far removed from Polanyi's "personal knowledge", and the passion which is the prerequisite of all true advance. There must be conviction that there is a problem to be solved, coupled with the will to solve it. (Incidentally, the joy attending success is almost wholly aesthetic, in a realization of the beautiful.) And this cannot be done from inside. Mrs. Bowes might have mentioned Godel's theorem as her perfect example: 'inside' arithmetic we are plagued with incompleteness, whereas 'outside' we can at least do our sums. Which is as much as to say that, as such, metaphysics is unlikely to make progress, and the common transliteration as 'beyond physics' is seriously misleading.

Mrs. Bowes refers, however, to the work of David Bohm, who concludes that Nature is qualitatively infinite. He propounds the existence of various levels in physics (both classical and quantum), and suggests a further very deep level at which determinate factors are effective, resulting in the accepted laws of probability and the quantum higher up. Whether this is so or not remains to be seen, but one thing is certain—and in tune with all metaphysical thought—and that is that no event in Nature is isolated, so that if in fact something unknown is going on down below, then known phenomena, and the laws which we believe they obey, are influenced accordingly.

The contrast comes out strongly between metaphysics and common sense. The point is well taken in that it is unwise to identify science with common sense, for much goes to show that the most fantastic prognostications of theoretical physics have turned out to be correct at the expense of ordinary explanation. Nevertheless, applied science functions, but this is largely because it is like doing a large-scale exercise or example, based on theoretical knowledge, from which success follows consequentially from a grasp of essentials.

*The Foundations of Metaphysics in Science* is written from a different standpoint. Prof. E. E. Harris is not primarily concerned with the existence of metaphysics as with the way in which he finds it embedded in much of science itself. In fact, what empirical content the subject possesses resembles the natural philosophy of Scotland, which indeed covers much observation and experiment. It is clear that a comprehensive view, synoptic in character, is necessary—as Plato maintained—if whatever total knowledge is accessible to us is not to be partly lost through specialist fragmentation. Besides, it is salutary to examine scientists' own credentials, which they are unlikely to do for themselves beyond the immediate needs of their own investigations. This is the general

task, divided into four main parts—(1) "The Physical World"; (2) "The Realm of Life"; (3) "Mentality"; (4) "Outline of a Metaphysic". These headings are enough to show the scope which the book is intended to embrace. It is very readable, even though there is a fair proportion of paste and scissors, with a slight tendency to write round the references. In dealing with the question of intelligence, a warning is given of the effect of drawing a sharp line between logic and psychology, which is so marked a feature of recent discussion. This is the result of a determination to avoid psychologism, the pet aversion of the phenomenologists and the Husserl school. The principles of organization are eliminated, and with them purposeful thought. Broadly, the *Gestalt* concept bears up well: it has seen many modifications since the days of Wertheimer and Koffka, but its integrative features are still valuable, much more indeed than mere 'and-summations'. Mozart (quoted by the author) would survey a musical composition "all at once", the whole being instantly established.

The unique position of entropy, to which reference has already been made, appears as the connecting link not only between metaphysics and science but also between our conception of the living and the non-living, which is roughly that of its dominance in open and closed systems respectively.

The wonder is that the living organism is so constructed as to be a means whereby entropy can not only be held constant but also in some cases even decreased. This is what the communications engineer strives to do by making use of negative entropy,  $K \log 1/D$ , wherein  $D$  is a measure of noise. Apart from the mathematical formalism, we begin to see in organization a signpost to a better understanding of meaning and perception. Naturally, once this connexion between entropy and living activity is realized, there is scarcely any limit beyond which it is not applicable.

Prof. Harris makes the point that modern symbolic logic, with its great capacity for preventing mistakes, adds no contribution to the pressing need for a science which treats of what organization is supposed to do, namely to set up the forms and principles of thinking. Ethically, as the author says, it is only at the heights of human effort that, due to such vast complexity, aberrations can occur at all. It is still true that man tends to kill the object he loves.

The thesis which these two books are written to defend—essentially a study of contrasts—is best summed up metaphorically in the words which "My Lady Philosophy" used to console Boetius in his prison cell at Pavia in A.D. 524. She said to him, "I will show thee the way which shall carry thee home", which is good and useful science. But she added, "I will give thy mind wings to be raised aloft", which is metaphysics. F. I. G. RAWLINS

## TEACHING RELATIVITY

### Introduction to General Relativity

By R. Adler, M. Bazin and M. Schiffer. (International Series in Pure and Applied Physics.) Pp. xv + 451. (New York, Toronto, London and Sydney: McGraw-Hill Book Company, 1965.) 100s.; 12.50 dollars.

GENERAL relativity has become a popular and widely understood subject in the past 20 years. As a result there have been a large number of books on the subject, some of them presenting collections of original work, and others presenting a view of the whole subject from one particular point of view. The present book differs from all recent books (except perhaps that of Synge) in being a genuine text-book. It is based on a course of lectures, given at Stanford University, by Schiffer. The aim of the authors was both to direct the attention of mathematicians to a fruitful field of research and simultaneously to provide the physicists with a simple introduction to the powerful mathematical methods used in general relativity.

Great care is taken to explain the motivation for everything that is being done, and the whole theory is set out with great clarity. After an introduction dealing with non-Euclidean geometry the tensor calculus is set up. The notation is the classical one with suffixes, no attempt being made to bring in the exterior differential calculus. The relationship of tensor calculus to physics is introduced by means of Maxwell's equations in a flat space and also through a discussion of gravitational red shifts in terms of a description of gravitation by means of a curved space. This brings the reader up to the position of having "general relativity without field equations". The usual arguments are now brought forward for the Einstein field equations as generalizations of Laplace's equation. Here, however, the authors do not neglect to use the argument from the equation of geodesic variation which exhibits the connexion with Laplace's equation in its clearest form.

Having now formulated the theory, discussion on the spherically symmetric static solution and the linearized field equations follow. After the derivation of the Schwarzschild solution there is a very careful description indeed of the present position of the theory with regard to the three so-called 'crucial tests'. A particularly interesting chapter follows, on the mathematical structure of the field equations in relation to the initial value problem. The characteristics and the bi-characteristics of the equations are exhibited with great clarity. The authors elect to omit the general (Fourès) proof of the existence and uniqueness, but they do give the particular result of Lichnerowicz (that a static empty universe which is flat at infinity is flat everywhere). It will give an idea of the completeness of the treatment to mention that this chapter concludes with a proof of the maximum principle for the generalized Laplace equation (that is, Earnshaw's theorem in curved space).

There are also chapters on conservation laws, cosmology and electromagnetism (including Weyl's theory and the already-unified theory of Rainich and Wheeler). The book is beautifully printed and has an excellent index.

C. W. KILMISTER

## THE SUN

### A Star Called the Sun

By Dr. George Gamow. Pp. xiii + 208. (London: Macmillan and Co., Ltd., 1965.) 35s. net.

DR. GAMOW has written an entirely new book on the subject of his earlier work "The Birth and Death of the Sun", and has incorporated an account of the advances in solar research which have occurred in the interim.

The book begins with a survey of man's attempts through the ages to answer such questions as how far the Sun is from the Earth, how large it is and how hot. Then follow chapters on the solar spectrum and what it tells us about the composition of the Sun, the turbulent solar surface, its atmosphere and its corona, and its hot interior. We are reminded of Dante on his journey to the inferior regions: "I would have cast me into molten glass to cool me, when I enter'd, so intense rag'd the conflagrant mass". After analysing the sources of stellar energy at different stages of the life of a star, the author compares the Sun with other stars and explores the nature of such old ones as red giants, white dwarfs and supernovae, the stars that "die glamorously". The last section of the book, on the origin of stellar families, shows that at least one billion stars in the Milky Way may possess planetary systems like that of our Sun (an American billion is a thousand million). Dr. Gamow is an expert in this branch of astrophysics and, as is expected, the sections that deal with the evolution and decay of stars are accurate, written with conviction, and fascinating.

Some of his statements concerning fundamental physics are not always so happy. For example, the 'decay period' [sic] of radium is given as 1,840 years, and two pages

further on the 'half-life' appears as 1,590 years. Dr. Gamow seems to have forgotten that the original product of the mines of Joachimsthal (given as Joschischal) was silver—and hence the name of his country's best-known money unit—and not uranium. The style is popular and sometimes racy. Occasionally it will offend the English reader who has some feeling for his Mother tongue, but on the whole, in spite of his "oodles and oodles", the author has avoided the ambiguities and half-statements which are a feature of so many attempts to vulgarize science.

The book is well produced, with good plates, diagrams and end-plates. W. L. SUMNER

## VIRUSES INFECTING PLANTS

### Plant Virology

Edited by Dr. M. K. Corbett and Dr. H. D. Sialer. Pp. xvii + 527. (Gainesville: University of Florida Press, 1964.) 12.50 dollars.

THIS valuable summary of modern information regarding viruses infecting plants and the diseases caused thereby was compiled from a series of lectures by specialists, delivered during the 1963 Southern Regional Graduate Summer Session in Plant Virology at the University of Maryland. After a historical introduction by one of the editors the various symptoms by which virus infection of plants is expressed are summarized by F. O. Holmes and the means by which viruses can be transmitted from plant to plant are described by R. W. Fulton, with comments on inhibiting factors and on the mechanism of infection of an individual plant cell. The technique of identification of a plant virus is discussed by A. F. Ross, followed naturally by a chapter on virus strains, mutations, acquired immunity on the part of the host and interference by one virus with multiplication in the host by an unrelated virus (W. C. Price). Next B. D. Harrison summarizes recent information regarding the transmission of plant viruses in soil. Two groups of nematode-transmitted viruses are recognized, one with polyhedral particles, the other with tubular particles. Both the viruses and the nematodes have wide host ranges, ensuring survival on weed hosts while virus-immune crops are being grown on the contaminated soil. Transmission of lettuce big-vein virus and tobacco necrosis virus appears to be assisted by zoospores of the chytrid genus *Olpidium*. Susceptible plants may become infected when grown in soil to which tobacco mosaic virus has been added, but it is still not known whether any vector is involved in this instance.

Two chapters follow which deal with the mechanism of virus transmission by insect vectors. R. H. E. Bradley concentrates on the precise method of stylet transmission on the part of aphids, a process apparently beset by so many difficulties and inhibiting factors that it seems astonishing that any aphid ever succeeds in transmitting any virus. K. Maramorosch summarizes the less-extensive work on so-called 'circulative' and 'propagative' viruses, which are not carried immediately on the stylets but are accumulated in the insect's tissues, either multiplying there or not, and afterwards re-introduced into a host plant by the insect. The group includes a few aphid-borne viruses, notably that of potato leaf-roll, and also viruses transmitted by treehoppers, leafhoppers, whiteflies, mealy bugs, thrips and mites. Some of these viruses appear to be in some degree pathogenic to their vectors, others may possibly be in some way beneficial to an insect which ingests them.

The following seven chapters are perhaps those of most general interest since they deal with the nature of viruses themselves. Methods for assaying plant viruses are described by D. A. Roberts, with emphasis on the local lesion technique, virus purification techniques by R. L. Steere and serology by E. M. Ball. The principles of electron

microscopy and their application to virus research are summarized by C. E. Hall, followed by a detailed account by D. L. D. Caspar of modern inferences regarding the structure and function of regular virus particles. These consist essentially of a ribonucleic acid chain (or deoxy-ribonucleic acid in some animal viruses) enclosed in a regularly constructed coat of protein units, called rather unhappily the 'capsid', the shape and structure of which are characteristic of the virus. The shape of virus capsids is comprehensible if it is accepted that the most probable minimum energy designs for surface crystals composed of a large number of units are tubes with helical or cylindrical symmetry and closed shells with icosahedral symmetry. Each of these types of pattern is now known to be adopted by and characteristic of different plant viruses and, even though the morphologies of helical and icosahedral virus particles appear very different, it seems that the principles applied in their construction are the same. Unfortunately the morphology of a virus particle is not necessarily an indication of its relationship with other viruses. Since there are only 230 types of crystal lattices it is not surprising that chemically unrelated compounds can form crystals with identical symmetry and the structure of biologically unrelated viruses, for example, poliovirus and turnip yellow mosaic virus, may be based on very similar designs. The helical structure of the tobacco mosaic virus rod is described in great detail, with interesting indications of small differences in the arrangement of protein units in different strains of the virus. Next C. A. Knight elucidates the structural biochemistry of plant viruses, both as regards the construction of viral proteins and the fine structure of the ribonucleic acid chain. Finally, W. N. T. Takahashi discusses the biochemistry of virus infection and such information as exists regarding the synthesis of viral proteins and virus particles within the host cell.

Three final chapters summarize methods for control of plant virus diseases (L. Broadbent), frankly facing the fact that quarantine may delay but cannot prevent the spread of viruses around the world to a maximal distribution determined by the geographical distribution of their hosts and vectors. F. C. Bawden speculates on the origins and nature of viruses and the application to virus studies of the principles of molecular taxonomy is discussed by F. Lanni.

An appendix contains two papers on non-plant viruses: virus diseases of arthropods by K. M. Smith and an introduction to the tumour viruses by R. A. Manaker.

Each chapter is followed by a comprehensive bibliography. R. W. G. DENNIS

## GOLD

### Gold

Recovery, Properties, and Applications. Edited by Edmund M. Wise. Pp. x + 367. (Princeton, New Jersey, Toronto, New York and London: D. Van Nostrand Company, Inc., 1964.) 93s.

THE metal gold has had a special place in civilized communities even from the most ancient times. It has been known to man for 6,000 years, and rivals copper as the first metal ever to be used. Early applications became possible because the gold occurred naturally in the metallic state in the beds of streams and alluvial sands in an easily recognizable form. Large pieces could be hand-sorted from neighbouring rocks, and fine particles trapped by washing gold-bearing sand over fabrics or animal fur. Sheepskin was popular for the latter purpose, and it seems probable that the 'Legend of the Golden Fleece' arose in this way. The gold was used in the earliest times exclusively for ornament, and was sufficiently ductile to be hammered into the required shapes without the need for sophisticated metallurgical treatment. Its attractive appearance, relative rarity, and chemical inertness led naturally to it being a prized possession, and to its use as

a medium of exchange for goods, and as a coinage. The function of gold as a monetary standard has continued up to the present time, and it has become the yardstick by which national currencies are measured.

The monetary uses of gold, and their influence on human behaviour (for example, as a brief glance at almost any television Western will show), have tended to obscure the applications of the metal in other fields. Broadly speaking, these applications stem from the ability of gold to resist many corroding environments, and from the ease with which it may be worked. Such properties lead directly to its use in electrical contacts, electron tubes, conductors, resistors, and thermocouples, where great precision and reliability are vital. A large part of the world production of gold, in fact, now goes into non-monetary uses. Dr. E. M. Wise, the editor of *Gold*, has studied and worked on the properties of the metal for many years, and he and his contributors have set out here to collect together for the attention of engineers, chemists, metallurgists, physicists, dentists, and those in the medical profession, the properties and applications which are of relevant interest.

The book contains twenty-eight chapters and includes descriptions of the sources of gold, the extraction, mechanical, physical, chemical, and metallurgical behaviour, the applications in electrical engineering, dentistry, jewellery and medicine, and special uses such as an additional element to glass, in the form of very thin films, and as a solder. Methods of chemical analysis, an important subject in view of the necessity of keeping account of the metal, are also included. The book is provided with ample lists of references, and I am not aware of such a comprehensive treatment in any other volume. It is expensive, but as it is a reference work rather than a book for the general reader this is probably not a disadvantage. It will certainly find its way to the library shelves of all organizations dealing with the metal, since it is useful to remember:

"Foul cankerous rust the hidden treasure frets,  
But gold that's put to use more gold begets".

J. A. CATERBALL

## THE BIOCHEMIST'S 'VADE-MECUM'

### Methods In Enzymology

Vol. 6. Edited by Sidney P. Colowick and Nathan O. Kaplan. Pp. xxiii+1054. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1963.) 200s.

THIS volume completes the supplement to the original treatise "Methods in Enzymology" (Nature, 177, 810 (1956); 178, 509 (1956) and 181, 1431 (1958)) and, like the earlier volumes, has been edited by S. P. Colowick and N. O. Kaplan. The editors have brought together an impressive list of 147 authors who have between them contributed 127 articles. These contributions are grouped together under three major headings; the first two deal with the preparation and assay of enzymes and substrates, and the third with special techniques used in enzymology. The enzymes included in this volume are those concerned with nucleic acid, phosphate, coenzyme and vitamin metabolism and the respiratory enzymes. Other enzymes have been dealt with in the previous volume. The preparation and assay of substrates were not included in the first volume of the supplement and so there is complete coverage of the recent progress in this field. The final section is entitled "Special Techniques" and, besides descriptions of more general methods of protein analysis, includes articles on the esoteric techniques involved in neutron-activation chromatography of phosphorus compounds and in the application of nuclear magnetic resonance and electron spin resonance to enzymology.

With such a large number of authors contributing to this volume there is some variation in the style and standard of the individual articles, although in general

the latter is high. There is usually an introductory paragraph to each contribution describing the enzyme or substrate and giving the principles involved in the assay. The experimental procedures are given in detail with adequate reference to the original literature so that, if problems arise in following methods given in the book, the individual worker can readily turn to the original paper. The grouping of methods under the general titles 'enzymes' and 'substrates', although in general it is satisfactory, does lead to minor inconveniences. For example, polynucleotide phosphorylase, RNA polymerase and cell-free protein synthesis directed by messenger RNA, all occur in the first 25 pages, yet we have to turn to page 713 for the synthesis of synthetic polyribonucleotides. Similarly, the isolation of DNA is on page 726, the enzymatic preparation of polydeoxyribonucleotides on page 718 and the DNA polymerase on page 34.

Throughout this volume the editors have allowed the use of trivial names for the enzymes, and it is unfortunate that, two years after the publication of the report of the Commission on Enzymes, a book of this importance can be written in which the systematic names and numerical code numbers for the enzymes are not used. Apart from this criticism this volume maintains the standard set by the editors in the previous volumes and together with them provides an excellent laboratory manual for all biochemists who require detailed working instructions for the preparation and assay of enzymes. D. KERRIDGE

## A SURVEY OF MANAGEMENT ATTITUDES

### Thrusters and Sleepers

A Study of Attitudes in Industrial Management. (A PEP Report.) Pp. 295. (London: Political and Economic Planning; and George Allen and Unwin, Ltd., 1965.) 35s.

WHILE much is said and written about the influence of management on productivity, little systematic investigation has been carried out to determine how far managers in fact achieve a high and sustained growth rate for their firms. There should be general approval, therefore, for this report of a survey carried out by P.E.P. into management attitudes and practices and their effects on a company's prosperity. Firms selected for study included those whose management attitudes and practices were likely to be conducive to growth and these were compared with firms whose managers were thought not to possess such attitudes.

The choice of firms was decisive. Expert opinion was consulted about those firms which were expected to be prospering in ten years time and, in contrast, the survey included firms of similar size and operating conditions but whose prospects appeared to be unpromising. Altogether, eight firms were visited in each of six varying types of industry which included old and new, science-based and non-science-based, contracting and expanding, capital and consumer goods, craft and mass production industries, localized and non-localized industries and American-influenced and wholly British companies. The industries finally selected were wool textiles, machine tools, ship building, electronics, domestic appliances and earth-moving equipment. Each company was visited for two days, executives were interviewed, much published material about the companies was read, and accounts were analysed.

The research teams investigated a number of factors which are in some way associated with improved productivity. Among them are the systematic development of junior and middle managers and the introduction of modern management techniques. The latter includes mechanization, work study, operational research and accounting techniques like budgetary and cost control. Frequently these are introduced into companies by management consultants and, consequently, the use made

of consultants was taken as a further means of determining management attitudes. The attention paid to research and development, marketing and exporting was also examined. In all, a total of 59 factors was built up. Firms whose managers reacted positively to them were described as 'thrusters' and those reacting negatively as 'sleepers'; there were many intermediate grades.

In itself, such a survey would have been inconclusive. 'Sleepers' could fairly claim that, in practice, the aggressive and busybody 'thrusters' might achieve no greater commercial success than the firms whose pace was based on that of traditional slow growth. Despite all the difficulties of measurement, therefore, the investigating teams analysed the companies' financial results to determine the compound average increase in capital employed and the average return of earnings (pre-tax profits) to capital employed over the previous 5 and 10 years. Comparisons showed that, in nearly all cases, 'thrust' in management is accompanied by commercial success and that 'sleepy' management leads to little company financial growth or reward.

Despite all its inherent difficulties and limitations, this is another example of the kind of survey which P.E.P. does superlatively well. Prof. J. R. Parkinson, Anthony Gater, David Insull, Harold Lind, Peter Seglow and all who have contributed to it deserve well of those who are concerned with the productivity of British industry. The survey has been well devised, and conducted and the findings should be used on all possible occasions as a means of prodding 'sleepers' into wakefulness.

The limitations of the book, however, become clearly apparent in the second half where the authors try to show how the findings could be applied to promote productivity. They describe Government measures which should be used to promote management education as well as incentives to encourage the acceptance of management techniques and the release of actual and potential managers to attend management courses. They recommend the setting up of "Industrial Boards" which could stimulate the development of modern techniques in recalcitrant firms in the same way that the "Industrial Training Boards are already giving assistance in the field of industrial training". In point of fact, no Industrial Training Board has yet made any impact on industry and the few inaugurated have not appointed their main officials. This, and other remarks, suggest that the survey has been carried out by men whose real knowledge of industry is slender and much of what they have accepted would have emerged differently from men possessing more detailed awareness of what really happens in industry. A great deal, for example, of what they call management development is open to question; their 'work study' is most often little more than the fixing of wage rates. The real opposition to marketing comes less from production managers and more from the sales managers who have no time for it. These are the kind of issues which make the book ring less than true and, unfortunately, detract from the value of what could have been one of the most penetrating analyses of British management conducted so far. T. H. HAWKINS

## INTRODUCTIONS TO GEOLOGY

### Geology

By W. C. Putnam. Pp. xii + 480 (illustrated). (New York and London: Oxford University Press, 1964.) 55s.

### An Illustrated Elementary Classification of Minerals, Rocks and Fossils

By H. C. Curwen. Pp. xi + 183. (Oxford, London and New York: Pergamon Press, 1965.) 42s.

SHORTLY before his death in March 1963, Prof. W. C. Putnam had all but completed the text of a course in geology for elementary students, which his colleagues in the University of California, Los Angeles, have

now seen through the press. The work is a fitting memorial to a distinguished scholar. Viewed as an introductory textbook for university classes it is unfortunately somewhat restricted in its coverage; for example, there is a full chapter on petroleum geology but no mention at all of ore deposits. Viewed as a text for collateral study, it merits high commendation. The style of the author is eminently readable if sometimes a little discursive, and it is with an infectious enthusiasm that he guides the reader through the study of earthquakes, volcanoes, deserts, glaciers, and so on, sometimes with digressions into literary and historical by-ways which text-book writers rarely tread. The book is graced by more than 200 illustrations, most of them half-page or full-page photographs of superlative quality which have not appeared elsewhere. The publishers are to be congratulated on the production, at a reasonable price, of a work which will do much to stimulate the interest of young people in earth science and which can be advocated unreservedly as a very suitable addition to every senior school library.

The Pergamon Press claims, for *An Illustrated Elementary Classification of Minerals, Rocks and Fossils*, that "the book will prove invaluable for use in universities, technical colleges, and schools of mines". It consists in large part of a collection of poorly reproduced and badly captioned geological photographs, principally culled (though this is not stated) from the albums of the Geological Survey of Great Britain and supplemented by tabular presentations of the properties of some rocks and minerals, cribbed from elementary text-books with the introduction of many mistakes, misapprehensions, and mis-spellings. Few pages are free from errors, some of which (for example, the claim that phosphate rock is metamorphosed guano) are repeated several times; and the standard of technical editing is poor.

C. F. DAVIDSON

## DATING EARLY MAN

### Frameworks for Dating Fossil Man

By Dr. Kenneth P. Oakley. Pp. x + 355. (London: Weidenfeld and Nicolson, 1964.) 45s. net.

A FOSSIL human skull has been discovered: how is it possible to tell its geological age? The various methods that can be used, their possibilities, limitations, difficulties, and results, are discussed in Dr. Oakley's most up-to-date book on this fascinating topic: *Frameworks for Dating Fossil Man*.

The classical method is by relative dating, where we can rely on geology, stratigraphy, palaeontology, palynology, geomorphology and archaeology. But an entirely new chapter has been opened by absolute dating—called by Oakley 'chronometric dating'—where radioactivity can be used, as in the carbon-14 and the potassium argon methods. While the first can only be used to date samples younger than about 50,000 years, the latter method covers a much wider range and can be used for the whole of the stratigraphical column. Here, at last, we have a yardstick for measuring geological time absolutely.

The book is subdivided into two equal parts, one on stratigraphical dating and one on archaeological dating. The reader is introduced in the first part to the problems of the chronology of Quaternary deposits in general, and separate chapters deal with the glacial chronology, the interglacial correlation and palynology, the correlation by fauna, the palaeotemperatures recorded in deep-sea cores, the changing sea-levels and the formation of river terraces. After this come more general chapters, in which Dr. Oakley treats certain important geographical regions: the terraces of the Somme in France, the glacial stages in Latium, Italy, the Pleistocene subdivision in Holland, and the post-glacial Baltic stages. Africa is discussed in

detail: pluvials and interpluvials, ancient lake-levels, fossils, soils, palaeoclimatology and climatic changes. In the second part mesolithic and palaeolithic cultures are considered, first in Europe and the Near East, then Africa, and finally Asia.

Palaeontologists will be pleased to find that for faunistic reasons the Günz glaciation as well as the whole of the Red Crag of East Anglia are now included in the Lower Pleistocene—the Villafranchian. Two curves demonstrating the palaeotemperatures (Figs. 5 and 12) have been taken from Emiliana, whose dates, as Dr. Oakley remarks, are not generally accepted. I myself believe that the estimated age for the Günz glaciation of 260,000–300,000 years is too small (the date given by Eriksen and Wollin in *The Deep and the Past* (1964) is 1,400,000). Leakey's Challeen skull from Olduvai, according to an improved dating by Curtis and Evernden, is now considered to be the same age as the *Pithecanthropus erectus* skulls from Java (500,000 years).

An important part of the book is the appendix. In the "Fossil Hominid Dating Tables" all known fossil hominids are listed according to group, country, site, date of discovery, name, stratigraphical and cultural and, if known, also the absolute date. Heidelberg Man is classified among the *Pithecanthropinae*; however, I am of the opinion that the name *Pithecanthropus* should be preserved, as Dubois gave a definition of the genus when describing the first specimen in 1894. The list of the *Australopithecines* to me seems open to discussion. *Meganthropus* from Java certainly does not belong here; I also think it premature to place '*Homo habilis*' from Olduvai here (this one name covers at least two different forms). It is regrettable that Dr. Leakey has already announced in the Press his new discoveries—even trying to give a new definition of the genus *Homo*—before making available a scientific description: it is, as yet, impossible to confirm or dispute his conclusions. From the list is missing the large upper molar from Olduvai, Bed II, attributed by Leakey (1958) to '*Homo sp.*', but which definitively has australopithecine affinities; it came from the same level as did Chellean handaxes and demonstrates the coexistence of Hominines and *Australopithecines*.

The foregoing should serve to demonstrate the broad base of Dr. Oakley's study, which indeed covers all modern aspects of dating our Pleistocene ancestors: tertiary deposits and possible human ancestors have been excluded. This readable book contains many tables and well-selected illustrations as well as maps and charts which make it easy for the reader to find his way through a great variety of subjects. But what makes the book especially valuable are the many illuminating notes and the extensive lists of modern references. The book presents an excellent review of the present state of affairs not only for the specialist but also for the interested layman.

G. H. R. VON KÖNIGSWALD

## LOOKING INTO THE FUTURE

### The Conquest of the Material World

By John Nef. Pp. xii+408. (Chicago and London: The University of Chicago Press, 1964.) 8-95 dollars; 67s.

DR. J. NEF has devoted many years to the study of social history of industrialization from the earliest times, and he has thrown much fresh light on the factors that have been involved by his great learning and penetrating analysis. He is the founder and chairman of the Committee on Social Thought in the University of Chicago, and is the driving force behind the recently formed Centre for Human Understanding at Washington. The subject of its last international meeting was "The Building of Bridges of Understanding" between nations at different stages of development. Dr. Nef seems to have been

surprised that the questions uppermost in the minds of the emergent nations in Africa, Asia and Latin America were concerned with the industrialization of their countries—how fast should it proceed and how far should they retain their old traditions even if this involved slower achievement of the material wealth that they are all seeking.

In *The Conquest of the Material World*, Dr. Nef has collected a number of key essays relevant to these problems, several of them having been re-written. In them, he traces the development of our industrialized civilization in Western Europe, which Nature has endowed with such varied and abundant mineral resources. "The conquest of this underground wealth by the Western peoples has been inseparable from the unprecedented power obtained by men in recent centuries over the physical world." The early chapters deal with mining and metallurgy in medieval society, with industrial Europe at the time of the Reformation, with the growth of large-scale industry in Britain between 1640 and 1840, and the contrast between industrial growth in Britain and in France. Dr. Nef then comes to the heart of the matter in his studies of historical interrelationships, in which he relates novel developments in industry to other kinds of endeavour, religious, monetary, scientific and governmental. His aim is to bring these diverse strands of history into a new unity that has hitherto been missed. This ends with an account of the influence of the political and industrial development in Britain and France on the drafting of the American Constitution. It omits, however, any detailed consideration of the quickening of the rate of change of the whole world economy due to the impetus given by the two great World Wars to the effort devoted to scientific research and development and to the desire for national independence.

In his epilogue, Dr. Nef looks into the future and states very clearly his own faith. He rejects the cyclic point of view of historians like Gobineau and Spengler, who regard history as the inevitable result of predictable forces.

He ranges himself with de Tocqueville against Gobineau in his belief "that the conquest of the material world has come out of human efforts never made before and out of a new hope in human nature which the future will either destroy or sustain". "What is my position?" he asks; "essentially this: the rise, particularly during the 17th and 18th Centuries in Europe, of a society transcending national and even European boundaries, putting the tender virtues in the foreground as ideals to be sought after, a society bent for a time on settling by limited warfare the issues that divide parts of it, a society open to all the societies of the world, cannot be accounted for without the attempts made to realize in the world something of the love emanating from Christ. . . . Men and women everywhere are now confronted with dangers and blessed with opportunities greater than any that existed in the times of Gobineau. The way in which they meet these dangers and opportunities depends not only on the scientific and technological knowledge they possess but upon the beliefs they hold. . . . It seems probable that the future of the human race rests with conduct based on higher ethical and aesthetic standards than have ever prevailed in either private or public relations. If this is so, how can we reject de Tocqueville's testimony concerning Christianity? . . . However dangerous dogmatism based on religious faith may be, it is less dangerous than dogmatism based on the extension of science to matters upon which science cannot legitimately pronounce. . . . Having conquered the material world, men and women have now the mission of making it a more decent place for human beings to live in. In order to do this, they will have to conquer themselves."

This is a challenging book by an idealist, that comes at an opportune moment for this troubled and divided world.

HAROLD HARTLEY

### Nuclear Power Systems

An Introductory Text. By C. D. Gregg King. Pp. xiv+480. (New York: The Macmillan Company; London: Collier-Macmillan Limited, 1964.) 100s.

WHAT real purpose is served by adding yet another to the already considerable number of introductory texts in nuclear engineering is difficult to see. There is little new to say and no really different way of saying it, but still the books come.

*Nuclear Power Systems* adds nothing at all to the existing texts. It covers the, by now, conventional ground of nuclear and reactor physics, reactor control, shielding, materials, reactor types, thermodynamics, steam turbines, fluid mechanics, heat transfer and nuclear power plant design. It is even more conventional than most, in that much of the material in the latter half of the book is standard revision of the topics and is scarcely related to nuclear reactors at all.

There is a certain lack of exactness in some of the sections, which must inevitably lead to wrong impressions being given to someone using the book as an introduction to the subject. For example, in the first mention of the multiplication factor, the critical condition is given that it shall be equal to unity, without any qualification that this either relates to its effective value or to an infinite system. There is a statement that "all neutrons in the moderator entering the fuel lump having the resonance energies are absorbed in the outer portions of the fuel lump". Then, as another example, what is now almost a standard schoolboy howler is repeated. This is the mistaken belief that the reason that Xe-135 builds up on shut-down of a reactor is because the I-135 half-life is less than the Xe-135 half-life. Despite the fact that the book is well produced it cannot really be recommended, bearing in mind the number of excellent texts there are already covering very similar ground. J. F. HILL

### Die Rohstoffe des Pflanzenreichs

Von Julius von Wiesner. Fünfte Auflage herausgegeben von Constantin von Regel. Lieferung 3: Organic Acids. By G. C. Whiting. Pp. 194. (Weinheim: Verlag von J. Cramer, 1964.) n.p.

THIS paper-backed volume reviews the properties, distribution and, in some cases, the industrial importance of the organic acids occurring in plants. Aliphatic and alicyclic acids are accorded the most space (some 54 and 20 pages, respectively) while aromatic, heterocyclic and amino-acids take up the remainder (6, 8 and 10 pages, respectively). The literature list includes 1,157 references, but few publications subsequent to 1961 are given. Plant names and the organic acids are separately and fairly fully indexed.

The book should be of considerable value as an information source, but the coverage is rather uneven and is clearly not comprehensive; unfortunately, no indication is given of the intended scope of this monograph. The approach is classical in its factual emphasis and there is little mention of the overall biochemical significance of the acids and their distribution. G. EGLINTON

The Problem of the Minimum of a Quadratic Functional By S. G. Mikhlin. Translated by A. Feinstein. (Holden-Day Series in Mathematical Physics.) Pp. ix+155. (San Francisco, London and Amsterdam: Holden-Day Inc., 1965.) 8.95 dollars.

THE process of solving a linear partial differential equation with given boundary conditions by minimising a suitable integral has a history which goes back at least as far as Riemann's method for solving Dirichlet's problem for Laplace's equation; Euler's variational condition leads back from the integral to the differential equation. More generally, there is a connexion between the linear differential equation and the minimal condition for a quadratic functional; and quadratic functionals at

once suggest the use of Hilbert space and the cognate theory of operators. Moreover, it is reasonable to hope that this concept may help in dealing with a delicate existence problem: Does the minimising function possess derivatives of an order sufficiently high to ensure that the terms in the differential equation have a meaning and that the equation is satisfied?

A number of Prof. Mikhlin's books have already been translated into English, and this is a welcome addition. In the first chapter he sets the variational scene; the second chapter contains some preliminary work, chiefly about operators. The meat of the book is in Chapters 3 and 4, where the method is first applied to equations of elliptic type and then shown in action in solving the basic partial differential equations of elastic equilibrium under prescribed conditions on the boundary displacements or stresses.

The reader needs to know something about the theory of operators in Hilbert space, and in addition might well be helped by making a parallel study of Sobolev's monograph on the applications of functional analysis in mathematical physics, recently translated for the American Mathematical Society. The clarifying and systematizing power of functional analysis makes it one of the most efficient tools of the present-day mathematician, in both pure and applied mathematics. T. A. A. BROADBENT

### Annual Review of Microbiology

Vol. 18. Edited by Charles E. Clifton, in association with Sidney Raffel and Mortimer P. Starr. Pp. vii+394. (Palo Alto, Calif.: Annual Reviews, Inc., 1964.) 8.50 dollars.

THIS volume continues the annual series of reviews which by now is so well known among research workers and university teachers as to require no introduction. The reviews, as is usually the case with volumes in this series, are written in an extremely condensed manner, which means that, although most of the relevant literature is adequately discussed, the reviews make rather daunting reading.

The precedent of the earlier issues is continued by covering a wide range of microbiological topics of interest to workers in both the pure and applied aspects of the subject. In all, fourteen topics are reviewed, three mainly of virological interest, two genetic, five biochemical, one immunological and two taxonomic.

It is virtually impossible for one person to give a critical review of a collection of articles of this kind, quite apart from the question of whether it is desirable to review a review. Enquiry among specialists in the various topics covered by the volume suggests that each one is valuable and covers the ground well. The articles on the "Genetic Aspects of Metabolic Control" by W. K. Maas and E. McFall and on "Biochemical Mechanisms of Drug Resistance" by H. S. Moyed are of particular interest to me. The review on metabolic control is valuable in that it attempts to define the terms 'feed-back inhibition', 'repression' and 'induction', and then to present the experiments which throw light on the biochemical nature of these processes. In this field, the work of the group at the Institut Pasteur on the synthesis of  $\beta$ -galactosidase in *E. coli* has, in the past, often been discussed in reviews of this kind at the expense of work on other inducible and repressible enzyme systems in bacteria. This review goes a long way to correct this imbalance.

In the review on the "Biochemical Mechanisms of Drug Resistance", the author gives a full account of the methods whereby micro-organisms may become resistant to growth inhibitors. The review fails to consider, however, the frequency with which these various types of resistant strain arise. This is unfortunate, since information is highly important when considering the properties of successful antibacterial agents.

M. H. RICHMOND

# REMOVAL OF RADIONUCLIDES FROM THE BODY

By D. HYLTON SMITH and T. H. BATES

Health and Safety Department, Atomic Energy Authority, Chapelcross Works,  
Annan, Dumfriesshire

**DIRECT** evidence that incorporated radioactivity induces pathological change in humans includes, for example, the case-histories of the radium dial painters of the 'thirties, together with knowledge accumulated from the clinical use of isotopes. Indirect evidence has accumulated from investigations on animals, though much of this work is unrealistic in terms of human exposure. Few cases of human contamination in the nuclear industry have been recorded. However, as Catsch so rightly remarks, "even if the number of internal contaminations or poisonings by radioactive contamination could be minimized by means of effective protective measures and precautions, it would not exempt the scientist and physician from the necessity to test and develop appropriate therapeutic measures".

In contrast to external radiation where exposure occurs only for the period within the radiation field, internally deposited radionuclides provide a radiation dose continuously until they physically decay or unless they are removed from the body by a metabolic process. The relative danger depends on the effective half-life, the type of decay and the concentration of the radionuclide in a radiation-sensitive tissue. It is beyond the scope of this review to discuss detailed metabolism of the radionuclides, but it is important to stress that the critical organ can differ according to several physical and biological factors as well as the mode of entry into the body. Entry can be by inhalation, ingestion or wound contamination and, in practical terms, when considering radionuclides such as strontium-90 and plutonium-239 there are certain critical organs to take into account—lung, lymph nodes, bone and liver. Thus, inhaled plutonium dioxide is firmly fixed in lung and thoracic lymph nodes, injected or inhaled monomeric plutonium nitrate aerosol accumulates in bone while polymeric plutonium concentrates in liver. Strontium rapidly enters the skeleton whatever the mode of entry, being incorporated into bone crystals.

When an insoluble particle is inhaled, its site of deposition in the lung depends on its size. Particles less than  $1\mu$  in diameter will enter the alveoli. Here, they may be ingested by phagocytes which are able to migrate into the lymphatic circulation or they may become embedded in fibrous tissue. Larger particles tend to deposit in the bronchioles. The 'non-respiratory' bronchioles are lined with ciliated columnar epithelium and particles in this region are removed from the lung by ciliary action. The hazard then becomes one of ingestion if the particle is swallowed.

Bone metabolism is vaguely understood. Bone tissue is predominantly made up of hydroxyapatite crystals and collagen. Three types of cell are identifiable, each associated with a specific function. Osteoblasts are located on the growing surface of bone and synthesize collagen; osteocytes are osteoblasts that have become surrounded by their own calcified, secretory products; osteoclasts are giant cells associated with resorption of bone. The fundamental unit in bone is the osteon, and the degree of calcification of these units alters with age. The mechanism controlling bone growth is obscure, but it appears to be influenced by several humoral stimuli. One of three different metabolic states can exist at any time within bone. On active surfaces, the matrix is laid down as a border of uncalcified osteoid covered by active osteoblasts.

If the surface is quiescent, non-active osteoblasts lie against a calcified matrix. Finally, if the surface is resorbing it is covered with osteoclasts. The alkaline earth radionuclides, which follow the movement of stable calcium ion closely, concentrate on active surfaces, whereas plutonium-239 tends to concentrate on resting surfaces, possibly in combination with mucoproteins.

When a soluble radionuclide enters the body, transport and metabolic processes lead to its deposition in various sites including the critical organ. A knowledge of how this occurs is of fundamental importance in studies aimed at the therapeutic removal of the radionuclide. Such investigations have been carried out at Chapelcross using strontium-85 and plutonium-239 as an example of a transuranic element.

Mature female Sprague-Dawley rats were killed at intervals up to 48 h following the intraperitoneal injection of carrier-free strontium-85 as chloride or  $^{239}\text{Pu}$  as nitrate. Blood and tissues were analysed for activity in order to follow the kinetics of the distribution of the radionuclides and clearance rates from body compartments. Some of these results are summarized in Figs. 1 and 2. The specific activities of strontium-85 and plutonium-239 in blood reached maxima at 0.25 h and 1 h respectively. After approximately 2 h the linearity of the clearance curves plotted on a log-log scale indicates compliance with a power law. Very rapid transfer of

Fig. 1. Tissue fractionation of  $^{85}\text{Sr}$  in the rat

Fig. 2. Tissue fractionation of  $^{239}\text{Pu}$  in the rat

both isotopes is indicated but the longer duration of plutonium-239 in blood is of significance from the point of view of its therapeutic removal. Strontium is present predominantly in the plasma fraction of blood, both as free ion and protein bound; but the latter complex is easily dissociated since plasma samples subjected to dialysis were completely decontaminated. Hence the nuclide is readily available for clearance. Plutonium, on the other hand, is more strongly bound to protein in plasma since only 15 per cent was ultrafilterable. It appears to exist as a  $\beta$ -globulin or  $\beta$ -lipoprotein complex.

The clearance rates of the two isotopes from liver also illustrate a distinct difference. Whereas the clearance rate of strontium paralleled that from blood, the liver burden of plutonium increased over the period examined. Using the monomeric form, the liver contained 4.7 per cent at 48 h, although up to 70 per cent can be concentrated if the polymeric form is injected. The uptake figures into bone for both radionuclides show a rapid transfer from extracellular fluid, so that effective therapy should ideally be initiated during this period.

#### Use of Chelating Agents to mobilize Radionuclides

The principles of chelation chemistry have been applied to the problem of removing radionuclides from critical organs in recent years. Success depends on the formation of a blood-soluble metal chelate which is capable of crossing cellular membranes and of excretion in the unionized form by the kidneys.

The following remarks are intended only as an elementary explanation of chelation chemistry for those not acquainted with the principles. In a solvated metal ion  $M(\text{H}_2\text{O})_x^+$ , the formation of co-ordination compounds is dependent on the co-ordination number ( $x$ ), that is, the number of molecules of water bound to the ion. If this number is greater than unity and the metal ion forms one or more heterocyclic rings, the complex is called a metal chelate. Its formation depends not only on the co-

ordination number but also on the number of donor atoms of the ligand ( $L$ ). Because of its basic nature, being an electron donor, the ligand is associated with protons over a wide range of pH and thus the formation of a chelate is influenced by competition between metal ion and protons for the ligand.

Catech<sup>1</sup> has derived a formula for expressing the biological effectiveness of chelating agents. In the simplest circumstances, he postulates that the alkali metals and the trace elements in a biological fluid do not form chelates which can effectively compete with calcium ion. Thus, in measuring the ability of a chelating agent to combine with a radioactive metal,  $M$ , calcium ion is the only significant competitor. Catech, in a first approximation, assumes a simple  $LM:1L$  chelate and a  $1Ca:1L$  chelate to exist at pH 7.4, but the effectiveness of the ligand for the metal ion  $M$  is dependent on whether  $M$  is carrier-free or isotopically diluted. How this effectiveness varies with concentration of metal and ligand is shown in Fig. 3. The ordinates show the ratio of chelated to non-chelated metal ion  $(ML)/(M)$ , the abscissae show concentration (in moles/l.) of either  $M$  or  $L$ . If the metal ion concentration is low, the effectiveness of chelate formation increases linearly with ligand concentration (curve a). Conversely, this effectiveness decreases if the ligand concentration is constant (say,  $10^{-4}$  moles/l.) and the metal ion concentration increases (curve b).

Marked deviations from this theoretical concept are found in the living organism. The therapeutic effectiveness of a chelating agent demands a fairly constant and high extra- and intra-cellular concentration of the ligand. Unfortunately such levels are commonly associated with toxic effects. The maintenance of a high concentration is influenced by the rate of metabolism of the chelate, the rate of excretion and the stability of the chelate under extreme conditions of pH (for example, in the renal tubules). The ideal chelate should be metabolically inert and this is so for the polyaminopolycarboxylic acids. However, they are not stable at extremes of hydrogen ion concentration and may dissociate in both renal tubules and bone cells. No ligand has yet been synthesized which

Fig. 3. Dependence of chelation on the total concentration of the chelator and the metal  $a$ ,  $[M]_{\text{total}} = 10^{-10}$ ;  $b$ ,  $[L]_{\text{total}} = 10^{-4}$

will react specifically under biological conditions with a particular metal ion. In a complex biological environment such as plasma, many metal chelates can be formed at differing velocities of formation and stabilities. Thus the presence of competitive physiological chelators must influence the effectiveness of the artificial chelating agent, particularly if the radionuclide to be removed is carrier-free.

All the chelating agents claimed to be useful in metal mobilization contain oxygen, sulphur or nitrogen as electron donor atoms; a group at Aldermaston has studied the chemical characteristics of many of these chelators. The polyaminopolycarboxylic acids, in particular, ethylenediamine tetraacetic acid (EDTA) and diethylenetriamine pentaacetic acid (DTPA), are considered on chemical grounds to be applicable to biological media. These compounds are water-soluble, metabolically inert, but are relatively toxic when used at the highest permissible dose consistent with maximal removal of the radionuclide. Apart from toxicity, one serious limitation of the known chelating agents is that their effectiveness is profoundly reduced if treatment is delayed. Even the use of a pharmacologically active substance in combination with a chelating agent (for example, parathyroid hormone plus EDTA to remove plutonium-239 (ref. 2), diamox plus DTPA to remove cerium-144 (ref. 3)) does not modify this efficiency. DTPA may be cited as an exception to this in certain circumstances. Although disappointing results have been obtained using aerosol-DTPA to reduce lung burdens of plutonium-239, this radionuclide can be mobilized from bone after delayed intravenous or intraperitoneal DTPA. Results from a typical experiment in our laboratory are shown in Fig. 4 where increased excretion was produced after a delay of forty-three days. DTPA accumulates in intracellular fluids so that success in delayed treatment may depend on this fact. Esterified DTPA, which can penetrate cellular membranes more easily than DTPA, is possibly more efficient because of this property<sup>4,5</sup>.

Recently, a chelating agent, desferrioxamine methane sulphonate (FAB), has been claimed to be more effective than DTPA in removing plutonium-239 from bone<sup>6</sup>. This is at present being confirmed.

#### Attempts to Modify the Excretion of Radioactive Strontium after Modification of Certain Physiological Parameters

From the investigations, by many workers, on the removal of radionuclides deposited in the body, there has emerged the fact that the synthetic chelating agents so far

Fig. 4. Effect of DTPA on the retention of <sup>239</sup>Pu injected in the rat initially and after 43 days. Injected dose, 15 mld/kg. ---, Controls, —, treated.

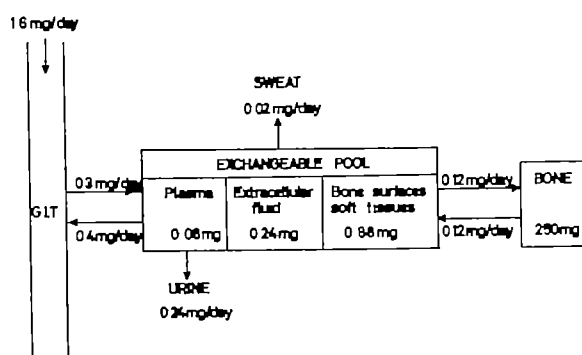

Fig. 5. Compartmental model for strontium metabolism in human adults

available are limited in application. In some cases, notably that of strontium deposited in bone, there are theoretical limitations to the efficiency of chelating agents because of the similar chemical properties of calcium and strontium. It is believed that the alteration of certain physiological mechanisms offers the most promising approach and a summary of our work is included. All experiments were designed to modify calcium deposition and resorption processes in the rat.

The rapidity with which radioactive strontium is transferred to bone is vividly shown in Fig. 1, 40 per cent being associated with skeletal tissue 30 min after injection.

Nordin *et al.*<sup>7</sup> envisage a two-compartment model in the metabolism of calcium. The first compartment is referred to as the exchangeable pool and includes the extracellular fluid calcium, the exchangeable intracellular calcium and a small fraction of skeletal calcium; it reaches equilibrium within 24 h. The second compartment comprises the skeletally fixed 'non-exchangeable pool'. Stable calcium leaves the exchangeable compartment by three routes—excretion, new bone formation and slow physical diffusion or exchange. Excretion is irreversible and is assumed to proceed at constant rate under normal physiological conditions. Bone formation and the physical processes, on the contrary, are potentially reversible and are variable parameters capable of determining the net transfer of calcium from the first compartment to the second. As a result of new bone formation and physical exchange, the bulk of the isotope is incorporated into bone mineral and, once this has occurred, the removal of calcium and, of course, associated radioactive isotopes is very slow. In the mature human, new bone formation is believed to occur at the rate of 0.01–0.02 per cent per day with the laying down of crystals in osteons at about 1 μ per day. Continual accretion and resorption are occurring, but the rate of this process declined with increasing age. The metabolic turnover of bone in a young adult is estimated at 10 per cent per annum. The metabolism of stable strontium, for comparison to calcium, is shown in Fig. 5. This is a compartmental model as designed by Dolphin and Eve<sup>8</sup>.

Success in removing bone-seeking radionuclides from the body is obviously dependent on initiation of therapy as soon as possible in order to prevent the transfer of loosely bound radionuclide to the firmly incorporated form. Thus the time-factor has an important bearing on the possible use of simple prophylactic measures before human exposure to short-term high occupational hazard and on the clinical value of any necessarily delayed therapeutic procedure.

Trusta<sup>9</sup> postulates that the formation of new bone begins with the maturation of the cartilage cell and the alteration of the matrix surrounding it to contend with the development of a vascular system which supplies the materials required for calcification. It is from the blood vessel walls that osteoblasts are laid down and lamellar bone formed. The factor inducing vascularization may be chemotactic in nature. Sobel<sup>10</sup> has shown that bone

collagen fibrils *in vitro* possess the property of nucleating hydroxyapatite crystals. Inhibition of this mechanism, which is responsible for calcification, would therefore prevent new bone formation. Fleisch and Neuman<sup>11</sup> have identified an inhibitor of this process in plasma which is inactivated by bone alkaline phosphatase. They suggest that normal calcification in bone is dependent on the local destruction of the inhibitor which they have tentatively characterized as a pyro- or poly-phosphate.

Fluoride and fluoracetate have also been shown to inhibit calcification *in vitro*, the former by blocking enolase activity at a concentration as low as  $10^{-4}$  M, the latter compound inhibiting enzymes in the tricarboxylic acid cycle, causing the accumulation of citrate in tissues<sup>12,13</sup>.

All these inhibitors were examined by us. Fluoride, fluorinated derivatives of metabolic precursors, pyro- and poly-phosphates were administered to rats either before, simultaneously with or after the intraperitoneal injection of strontium-85. The rate of excretion of the radionuclide was then determined by a whole-body counting technique. Fluoracetate, the phosphates and fluoride at a concentration in drinking-water below 75 p.p.m. did not accelerate the rate of excretion of strontium-85 compared with a control group of animals, but pre-medication for fourteen days with fluoridated water at a concentration of 150 p.p.m. significantly increased the excretion rate (Fig. 8). At this concentration no pathological changes were observed.

The process of bone resorption and remodelling is dominated by the osteoclast. This cell is controlled by parathyroid hormone which acts primarily by maintaining a steady state of supersaturation in relation to calcium and phosphate between bone and plasma, possibly by the localized production of citrate ion in areas of resorption<sup>14</sup>. Oestrogens and succinate ion may also create citrate accumulation<sup>15,16</sup>. In this respect, evidence is forthcoming which shows that citrate can dissolve hydroxyapatite crystals effectively<sup>17</sup>. Vitamin A may also be involved, directly or indirectly, in bone resorption<sup>18</sup>, either by modifying the action of parathyroid hormone or by increasing cellular permeability to allow migration of larger molecules.

Citrate is located in significant amounts on the surface of bone crystals, thus creating the conditions necessary for the localized metabolic acidosis necessary for solution of bone crystal. Citrate ion has unique biochemical properties. It has three carboxyl groups all of which are ionized at the pH of body fluids. It forms unionized but soluble complexes with the alkaline-earth metals. Therefore it behaves as a physiological chelating agent for mobilizing calcium and strontium ions.

Fig. 6. Effect of sodium fluoride in drink on  $^{85}\text{Sr}$  retention in the rat. ---, 1, 10 or 75 p.p.m.; —, 150 p.p.m.

Fig. 7. Effect of sodium citrate (8.5 mM/kg body-wt.) on  $^{85}\text{Sr}$  retention in the rat

Injection of trisodium citrate into animals given strontium-85 showed that provided it was injected intraperitoneally and within 30 min of the radionuclide, then a significantly increased excretion rate of the nuclide was possible (Fig. 7). We believe this effect to be due to chelation with that strontium contained in the exchangeable pool. Citrate is rapidly metabolized in liver and kidney and thus remains effective for a limited period after injection. Introduction of citrate prior to the radionuclide is valueless if the time-interval between injections allows for metabolism of the citrate. High intracellular concentrations of citrate can be maintained by prolonged intraperitoneal or intramuscular injection, but neither of these techniques proved to be superior to a single intraperitoneal injection.

The administration of citrate, parathyroid hormone, vitamin A, the induction of a generalized metabolic acidosis with ammonium chloride or a carbon dioxide respiratory acidosis had no effect whatsoever on the excretion of that strontium-85 firmly incorporated into bone. The results obtained with parathyroid hormone are surprising and further investigations with this hormone are in progress.

Attempts to stimulate increased excretion of extracellular fluid before the injected strontium-85 became firmly incorporated were made using a mercurial diuretic and hyaluronidase. The former substance acts by blocking renal tubular reabsorption and hyaluronidase increases cellular permeability, thus increasing the volume of the extracellular compartment to produce a diuresis. Neither of these compounds altered the rate of excretion of strontium-85, alone or combined with the various stimulators or inhibitors of calcification.

In the proceedings of a scientific meeting in 1962 held in Vienna, Loutit<sup>19</sup> emphasized the role of physiological mechanisms in removing radioactive strontium: "even when strontium is injected intravenously into the normal adult, only about 10 or 15 per cent is retained after a year, so that all these small factors (referring to renal and intestinal excretion) of the normal physiological function provide 70, 80 to 90 per cent removal of strontium. If each of the factors could be increased slightly, the gain by summation would be considerable".

This fact is illustrated in Table 1, which shows the excretion of radioactive strontium from rat. An attempt has been made to modify one of the excretion routes by selective blocking of renal tubular reabsorption which would reduce the body burden even further, provided that re-equilibration occurs rapidly between extracellular fluid and exchangeable calcium, and assuming that some radioactive strontium is present in the exchangeable pool.

Salicylate ion appears to induce this mechanism of tubular block as a delayed phenomenon. If salicylate is administered immediately after injection of radioactive strontium, the eventual excretion of this radionuclide is reduced compared with controls. However, if given after 24 h, it induces enhanced excretion. Factors other than renal may therefore be involved, but alteration of kidney function is suggested as the primary event. The influence of salicylate is shown in Table 2. Although isotopic dilution of radioactive strontium has been found to be ineffective if delayed<sup>20,21</sup>, some synergistic effect can be observed if it is injected with citrate or salicylate. A summary of the various treatments used is given in Table 3.

Table 1. DISTRIBUTION OF <sup>88</sup>Sr IN EXCRETA OF RAT (MEANS OF 20)

Period (days)	Per cent injected dose Urine	Per cent injected dose Faeces
0-1	18.8±6.8	12.0±1.9
1-2	4.5±0.5	8.0±2.0
2-3	2.4±0.5	2.5±0.7
3-4	1.0±0.1	1.1±0.1
4-7	1.5±0.4	1.5±0.3
7-9	1.1±0.5	1.1±0.7
9-11	0.7±0.3	0.4±0.1
11-14	0.6±0.1	0.7±0.1
14-16	0.7±0.1	0.4±0.1
16-18	0.5±0.1	0.5±0.1
18-21	0.4±0.1	0.5±0.1

Table 2. RATIOS OF <sup>88</sup>Sr ACTIVITY IN EXCRETA RELATIVE TO CONTROLS

Period	Na salicylate (200 mg/kg) daily		Sodium citrate 3.5 mM/kg initially and daily salicylate	
	Urine	Faeces	Urine	Faeces
0-1	0.89	0.69	2.24	0.49
1-2	3.25	1.08	4.17	0.78
2-3	3.75	1.03	4.80	0.81
3-4	3.51	0.88	4.09	0.74
4-7	2.20	1.13	2.20	0.72
7-8	2.01	0.96	1.88	1.10
8-9	1.57	1.10	2.50	1.00
9-10	1.66	0.99	1.68	0.96
10-15	1.37	1.20	1.60	1.18
	Best period		Best period	
15-17	0.74	0.68	1.10	0.37
17-18	1.38	0.96	0.66	0.72
18-21	1.60	0.80	1.80	0.21
	Weekend		Weekend	
21-22	1.12	0.61	1.00	0.91

Table 3. CLASSIFICATION OF TREATMENTS TRIED TO LIMIT UPTAKE AND REDUCE THE BURDEN OF RADIOACTIVE STRONTIUM

Inhibition of calcification	Stimulation of decalcification	Increase of membrane permeability	Selective renal tubular reabsorption
Sodium hexameta-phosphate	NH <sub>4</sub> Cl acidosis	Hyaluronidase	Acetazolamide
Sodium dihydrogen pyrophosphate	Respiratory acidosis	Anoxia	Mercuryl Sodium bicarbonate
Sodium tripolyphosphate	Parathyroid hormone	Vitamin A	Sodium salicylate
Sodium decapolyphosphate	Vitamin A		
Sodium fluoride	Oestrogens	DOCA	Isotope dilution
Magnesium fluoride	Sodium citrate		Stable strontium
Sodium fluoracetate	Sodium succinate		Stable calcium
	Sodium tricar-ballylate		

In conclusion, the most fruitful approach at present is that of combined therapy—early citrate treatment in the presence of carrier strontium, followed by late treatment with sodium salicylate. Efforts are now being directed to finding the optimum conditions of treatment and our most successful experiment is shown in Fig. 8. A significant reduction in body burden is possible after twenty-one days.

### Attempts to modify the Removal of Plutonium-239 by Modification of Certain Physiological Parameters

Several centres are studying the problem of plutonium-239 removal from the body. Progress in this field is reviewed in the Hanford Symposia of 1962 and 1964 (refs. 22 and 23). Success in mobilizing plutonium-239 depends on the critical organ in which it is deposited, and the development of a series of chelating agents has resulted in the evolution of a form of therapy for its removal from skeleton and soft tissues. However, the limitations of chelating agents have been mentioned previously in this review. No published record of attempts to alter

Fig. 8. Effect of combined treatments on retention of <sup>88</sup>Sr in the rat. A, Controls; B, citrate-succinate then salicylate; C, as B but with carrier strontium

the factors which control the metabolism of plutonium-239 is known and work in progress at Chapelcross is directed towards the application of such a concept as a form of therapy. A more serious problem of plutonium-239 contamination is that of the concentration of inhaled, insoluble <sup>239</sup>PuO<sub>2</sub> in the lungs and lymph nodes (Fig. 9). Little success can be claimed for the chelating agents<sup>24</sup>. Labelle and Brieger<sup>25</sup> were able to increase the clearance rate of radioactive particles from lung by inducing phagocytic activity, but Bair and Hennacy<sup>26</sup> using carbon aerosols were unable to confirm this finding.

Pulmonary vasoconstrictors, expectorants and mucolytic agents have been used without success, but the bronchodilator protocatechayl alcohol and the surface-acting polymer 'Phuronic F68' may have a marginal effect<sup>24</sup>. Some recent work by Heppleston<sup>27</sup>, with whom we are collaborating, suggests that phagocytic action may be induced within fibrous areas of the lung by means of physiologically occurring molecules. This work is in the initial stage of development.

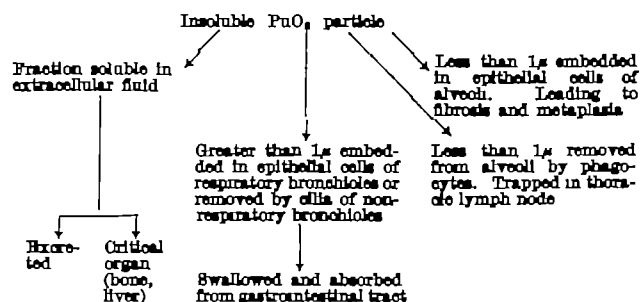

Fig. 9. Fate of inhaled plutonium dioxide

### Conclusion

This review is intended to place the problem of radionuclide contamination into perspective. Any treatment initiated by a clinician must be planned with the welfare of the patient at heart, so that risk and trauma are reduced to a minimum. The synthetically produced chelating agents have a place in therapy; but it is suggested that such treatment will not assume the same importance as it has in the mobilization of the stable metals from the body.

Successful elimination of any radionuclide should be possible, but it is essential to understand the physiological processes involved in radionuclide transfer and deposition. Only then can therapy be applied which is based on the delicate control of metabolic function so that selective

inhibition or accentuation of a particular pathway is achieved.

## OPERATION OF A 'LAW' OF PARSIMONY IN SHAPING ANIMAL LIFE-CYCLES

By DR. A. H. WEATHERLEY

Zoology Department, School of General Studies, Australian National University, Canberra

"Divvie a search," said the Irishman.

"Sure God can search for me if he wants me. My own belief is that he's not all that he sets up to be. He's not properly made and finished yet. There's somethin in us that drivin at him, and somethin out of us that drivin at him: that's certain; and the only other thing that's certain is that the somethin makes plenty of mistakes in thyrin to get there. We've got to find out its way for it as best we can, you and I . . ."

George Bernard Shaw: *The Black Girl in Search of God*

"In metaphysics my creed is short and simple. I think that the external world may be an illusion, but if it exists, it consists of events, short, small and haphazard. Order, unity and continuity are human inventions just as truly as are catalogues and encyclopaedias."

Bertrand Russell: *The Scientific Outlook*

IT is possible to class animal life-cycles either as relatively 'compact' or 'diffuse', giving these terms their normal respective meanings: 'closely packed together or condensed' and 'spread out, or not concentrated'.

As examples of the more 'compact' life-cycles we can turn to those animals the life-habits of which are generally considered to be prime examples of natural selection's tendency to favour parents which are thrifty and prudent regarding the welfare of their offspring. Here the mammals are obvious models. Bringing forth their young alive and often well-equipped for free life almost from birth, mammalian parents appear to safeguard their young against the rigours of the environment. Some care in rearing the young is also common to them, so by one means or another mammals are generally assured of a good start in life. Moreover, the young usually occupy much the same territory as the adults, often living side-by-side with them from birth. But if the mammals are such obvious examples of life-cycle 'compactness', so, too, are the many protozoans which reproduce by fission to give rise to two nearly identical individuals occupying essentially the same space that their 'parents' occupied. What could be more 'compact' than this? This also illustrates the non-phyletic nature of 'compactness' and 'diffuseness'.

I must make it clear that by 'diffuse' life-cycles I do not want to restrict my meaning only to animals with stages in their life-cycles which are spatially wide apart, but also wish to include those the life-cycles of which demand a more or less complex régime of conditions for the successive stages if they are to go to completion, and which may also involve considerable ontogenetic variation

between the stages. Thus, while birds that have breeding and rearing grounds far separated from the regions where the non-breeding adults pass their lives are obvious examples of the spatial separation of different parts of life-cycles, insects, molluscs, coelenterates and parasites can provide examples of the kind of 'diffuse' life-cycle in which varying conditions and much ontogenetic difference between various stages are seen. Some cicadas may have doubly 'diffuse' life-cycles in that the adults are markedly separated both in ontogeny and time from the egg stage, and indeed, many animals provide examples of these several aspects of 'diffuseness' within their own single life cycle.

Clearly, only the more extreme forms of relatively 'compact' or 'diffuse' life-cycle may be located readily within this system. All others will fit somewhere into the spectrum of possibilities between the two extreme conditions.

In contemplating animals with 'diffuse' life-cycles many people appear to feel either that there must be something (albeit often very subtly expressed) in their peculiar life-cycle characteristics of peculiarly high survival value to the species. Alternatively, they may think of such forms as biological curiosities—surviving forms the aberrancies of which reflect a strangely tortuous evolutionary history. Such views may be quite valid so far as they go, but what I wish to propose here is that animals with 'diffuse' life-cycles are evidences of the working of a 'law' of parsimony in evolution.

In philosophy the law of parsimony states that no more causes or forces should be assumed than are needed to account for the facts of a situation or set of events—which is scarcely a new concept. Aristotle enunciated it for biology and it lies at the basis of 'Occam's razor' and, therefore, of the scientific method itself. The law's operation in evolution depends on two principles basic to biological thought: the tendency of animal species continually to produce variation, and the action of natural selection.

Now the actual details of the multitude of life-cycles in existence, whether species are free-living or parasitic, whether growth occurs continuously or in a series of steps that involve moults or metamorphoses, are of secondary importance in the present context. Nor does it really matter whether reproduction is sexual, parthenogenetic, or the result of simple fission. What does matter is that, for a species to maintain itself in the face of both internal

and external factors which cause mortality, it must produce enough new recruits to replace the dead, and to do this enough older members of the species must remain alive to produce eggs or young. Of course, in certain species or at certain times the adults may all be dead long before the young they produce will themselves be able to reproduce.

Let us now consider the life-cycle of the Atlantic eel, typical of the more 'diffuse' type. The young eels migrate, or are passively transported by ocean currents, to the land masses around the Atlantic, when they may move up rivers and become mature. During this trip, profound physiological changes accompany the changing external conditions that the migrating or transported individuals must encounter. Adult eels, which cannot reproduce in fresh water, have to return to one main region in the Atlantic to breed, again involving a trip of remarkable length and duration (though it is only fair to point out that Tucker<sup>1</sup> recently proposed that only the North American adults of the Atlantic eel actually complete this journey). How can we make any sense of a life-cycle involving a journey of this sort?

Suppose we assume the ancestral eel stock to have been wholly marine. According to Bertin<sup>2</sup> this would probably be a reasonable assumption, as he proposed that eels (marine in origin) have become dispersed throughout the world's oceans, the adults gradually having acquired tolerance to changes in climate and salinity enabling them to invade many fresh waters, while the eggs and very young free-living stages are still confined to what are essentially their ancestral salinity and climatic types, which are themselves now found only in certain sections of the oceans. Indeed, Bertin actually wrote that: "Because their need of warmth at the time of spawning brings them back every year into the warm waters, it has been necessary for their larvae to adapt themselves to longer and longer journeys." This statement is probably correct, but it fails to satisfy analytically. Why has it been necessary for the larvae to adapt themselves to progressively greater journeys? After all, many fish of fairly recent marine origin have successfully invaded fresh waters with all the stages of their life-cycle.

I think this illustrates what every biologist knows full well: that the forces of natural selection act on animals at every stage of their life-cycle but that these forces are often quite different at the different stages, and of course the different stages represent different kinds of raw material on which natural selection can act. For example, an aquatic insect could succumb to the influence of some environmental factor during its nymphal aquatic existence or while it is a winged aerial adult or as an egg. Yet the environmental forces that can impinge on these three stages may differ profoundly from one another. Here I suggest that almost any degree of complexity, oddness—in short 'diffuseness'—may be present in a life-cycle which does not interfere with its completion at an ecologically satisfactory level. This is the parsimony principle at work.

Here, then, I am really suggesting that a way of thinking about life-cycles that seems prevalent to me should be inverted. For example, in considering the intricacies of a parasite's life-cycle or the spatially spread out life-cycles of many birds, many seem to believe them to be principally delicate and subtle adaptations to habitat or environment; perhaps, too, as indicative of trends towards certain kinds of biological perfection. But I would say merely that they should be regarded as causal outcomes of evolutionary development, given the particular characters of the evolving stock from which they came at the moment of its exposure to effectively selective forces. This does not mean that such intricacies are not cause for wonder or that they are not true adaptations in the usual sense. But I would like to escape from the notion (teleological in overtones) that Nature is always driving at something, which I think colours so much thought on these subjects

even in an age when science is supposed to have emancipated itself from teleology.

The essential task in species survival—completion of the life-cycle—can be done simply and 'compactly' or complexly and 'diffusely'. From the animal's point of view, that it is done at all is what matters. The details may be essentially irrelevant, in themselves (however interesting to us, in themselves), to this central and, perhaps, only purpose of survival in evolution.

Perhaps we can also apply this general method of thinking in a way which will prove useful in considering certain other features of animal life. In a recent discussion with colleagues at which some aspects of the life-cycle of a parasite were raised the question was posed of the utility to the parasite of a complexly multi-layered cyst. It was certainly valid to enquire, as was done, as to the various functions implied by the presence of this complex layer. But I wondered why the enquiry seemed limited by the assumption that several aspects of the parasite's integrity within the cyst were being safeguarded by the layer. I thought that there was no *a priori* reason for thinking that a multi-layered structure must function in more than one capacity. It may do; but this is a matter which only further investigation can decide. The parasite in question, when in the cyst, is very small, with a very low total number of cells. It seems to me that it might easily be more energetically efficient for it to secrete what impresses us as a complex covering, using more than one group of its small number of cells to do the job, than to opt for a simple covering which, if it were to be of the requisite thickness or strength, would be beyond the capacity of any one of its groups of secretory cells. The analogy between this problem and the question of life-cycles is just this: apparently complex life-cycles, which we may suspect express in some subtle fashion peculiar advantages in the lives of their possessors, may merely be doing a basically simple job in a roundabout manner. But doing it: that is the point.

Actually, it appeared likely that a main function of the cyst wall is to safeguard loss of water. It was, however, objected that evidence suggested that the cyst material was not an effective water-proofing agent, and that an additional layer of wax or fat would be needed for that. But again, this argument could be invalid. So long as the cyst wall is sufficiently effective in preventing loss of water for the encysted animal to survive in the actual conditions of its encystment and carry on to the next stage in its life-cycle, then the cyst wall has done its task, whether it be made of lipidal material, chitin, plastic foam or feather dusters!

Now what the eventual outcome of the investigation I have referred to here will be is irrelevant for my purposes. It will, in the end, be decided in the objective empirical manner of all biological investigations. But it is important that we formulate a correct approach to such investigations, and I have tried to show that there are two ways of looking at this problem. The first of these rather makes assumptions as to detailed and intricate functioning, arguing from *our* conception of the complex, the second allows for a simpler explanation, at least as a possibility. An investigator armed with both approaches would, I believe, be readier to design a programme of analytical research, that could consider several possibilities, and would be less likely to reach a possible impasse in his research because of looking for functions that may not in fact be implied, except in his own mind.

To return to life-cycles, it may be, of course, that a mammal, with elaborate associations of juvenile and maternal parts of the life-cycle, will manifest some general advantage over another animal which occupies much the same territory but the life-cycle of which is much more 'diffuse'. But there is surely no fixed rule about this. Many splendidly successful bird species breed in one hemisphere, but spend at least half of their lives in the other. The forces in evolution producing such life-

cycles have been the subject of endless debate, and may have to do with changing climates, movements of land masses and the like. But the interesting thing here is that whenever we postulate that this kind of stretching out of a life-cycle is to be explained in some such terms—within an evolutionary frame—we can cite other examples where animal groups have simply become separated from parent stocks, or represent surviving forms of a stock many of whose earlier representatives have become extinct, and yet do not have diffuse life-cycles.

Perhaps then we can put the matter like this: natural selection will be free to act independently on the various parts of the life-cycle of an animal; in some animals this will mean that entirely different selective forces will act on different parts of the life-cycle; yet so long as the selective forces are not so severe as to break any part of the life-cycle the species will be able to maintain itself. The particular (or peculiar) feature of a life-cycle that we examine will be the evolutionary result of a particular group of biological responses of a particular life-history phase to certain particular effects of the environment.

L. C. Cole<sup>3</sup> has attempted to show that life-histories of organisms always have meaning and significance in terms of the survival of the species. He dealt particularly with intrinsic rates of increase, with iteroparity and semelparity, to show the profound effects that these properties can have in the maintenance and growth of populations, and he sketched the evolutionary strengths and weaknesses which might be inferred about a species through their consideration. Nothing I have written in any degree disparages what Cole put forward, and I regard as great

the significance of his essay to ecology and evolution. But Cole was dealing with parameters of populations which govern numbers, and through numbers evolutionary success. In another sense Cole clearly showed that these parameters are also adaptations of the species to its environment and way of life, ecological adaptations rather than the morphological and physiological ones we are, even to-day, more used to, but adaptations nevertheless.

In the last analysis the continuance of both populations and species turns on the effectiveness with which life-cycles are completed, despite changing conditions. The extinction of both populations and species is a matter of broken life-cycles rather than death of individuals; that is what makes habitat destruction so sore a point with modern conservationists, and also what frequently places so difficult a burden on them in delimiting and defining habitat.

The ability of a life-cycle to maintain the existence of a population or species or an evolving stock of animals will depend on the genetics of the animal, the particular features of the life-cycle (including adaptations of greater or lesser perfection) at the moment of selection, and these determine what fraction of the population survives and, therefore, the character of the future population or those derived from it. But, as there are many ways to skin a cat, there are many ways to complete a life-cycle, and no animal group has a mortgage on the way to do this successfully.

## OBITUARIES

### Dr. Ricardo Zariquiey Alvarez

DR. RICARDO ZARIQUIEY ALVAREZ, who died at his home in Barcelona on January 27, 1965, was not only a well-known paediatrician but also an authority on certain Spanish Coleoptera, notably the Bathyscininae, and on the decapod Crustacea of the Iberian Peninsula.

Ricardo Zariquiey Alvarez was born in Barcelona on January 3, 1897, and was educated at the Jesuits school. After graduating with distinction in medicine at the University of Barcelona in 1918, he studied in Paris and Lausanne in order to specialize in paediatrics. Like his father, Dr. Ricardo Zariquiey Oenarro, whose medical practice he eventually took over, he was keenly interested in natural history. Together with his father, he made extensive collections of Coleoptera, especially cavernicolous ones, and in a series of papers published during 1917–27, he described many new or interesting species from a wide area of northern Spain. Other arthropod specialists have paid tribute to the two Zariquieys by naming three genera or sub-genera and twenty-eight species or sub-species after them. Their collection of Coleoptera has been bequeathed to the Instituto Español de Entomología, Madrid.

About 1934 his father became interested in the decapod crustaceans of which he amassed an extensive collection and on which he published nine papers before he died in 1943. Dr. Zariquiey Alvarez then devoted his leisure time almost exclusively to the Decapoda, although in 1944 he published a paper on the distribution of the dipteran genus, *Phlebotomus*, in Spain. When the civil war ended he built a holiday bungalow near Cadaqués on the Costa Brava, and during the next twenty years he made a thorough investigation of the decapod fauna of that coast from Port de la Selva to the Bay of Rosas. Visits to the fish markets of Rosas and Barcelona yielded some decapod species new to science or new to the Spanish fauna. Local fishermen brought him any unusual finds,

and various marine and fishery stations in Spain sent him material for identification.

Dr. Zariquiey was always rather diffident about his hobby, regarding himself as an amateur carcinologist, and frequently consulted specialists in the Paris, Leiden and British museums and elsewhere. He also invited a few specialists to his home in Cadaqués and it was there that the small "Groupe d'Études carcinologiques" was formed in 1955. The main object of the group, which met again in Barcelona in 1955 and in Naples in 1959, was the compilation of a critical check-list of the Mediterranean decapod Crustacea. Zariquiey's suggestion, based on an unsurpassed knowledge of the living animals, that some of the so-called variable species of the museum taxonomist were in reality mixtures of two or more species, met with initial scepticism. But later on specialists had to acknowledge the correctness of this view. His results were published in a series of twenty-five papers during 1945–64; his book on the decapod Crustacea of the Mediterranean coast of Spain (1946) will soon be superseded by an up-to-date revision of the Decapoda of the Iberian Peninsula to be published posthumously. The whole of the Zariquiey collection of decapods has been bequeathed to the comparatively new Instituto de Investigaciones Pesqueras, Barcelona.

In addition to his presidency of the Institución Catalana de Storia Natural, Zariquiey was closely associated with numerous scientific societies in Spain; he was a life-member of the Entomological Society of France and a member of the board of advisory editors of *Crustaceana* from its inception. A rather shy and retiring man, he was exceedingly kind and took a genuine interest in the work and personal affairs of the simple fisher folk from whom he obtained specimens. One had only to see him with his grandchildren to realize how good a children's doctor he was. Those of us who were privileged to visit him in his happy and most hospitable home will always

cherish the memory of those days at Cadaqués; his enthusiasm for crustaceans was most stimulating. Our deepest sympathy goes to his widow, Señora Mercedes Colom de Zariquiey, to whom he was devoted, and to his son, his four daughters and their families.

ISABELLA GORDON

### Mr. I. Izsak

On April 21, 1965, Imre Izsak, chief of satellite research and analysis of the Smithsonian Astrophysical Observatory and lecturer at Harvard University, Cambridge, Massachusetts, died of a heart attack at the age of thirty-six. He was in Paris attending a COSPAR symposium on trajectories of artificial celestial bodies as determined from observations.

In the brief years of his scientific career, he had established himself as a pre-eminent authority on geodesy and had made significant contributions to the study of celestial mechanics. His death is both a deep personal tragedy and an irreparable loss to the scientific community.

Born in the small town of Zalaegerszeg, some two hundred miles from Budapest, Izsak attended the University of Budapest, where he worked in astronomy under the late Karoly Lascovszky (who also later joined the Smithsonian Astrophysical Observatory) and specialized in the investigation of variable stars and galactic clusters. Fleeing Hungary during the 1956 revolution, he began work on solar physics at the Zurich Observatory in November of that year. Two years later he emigrated to the United States and, after a brief period at the Observatory of the University of Cincinnati, joined the staff of the Smithsonian Astrophysical Observatory. On February 24, 1964, he became a citizen of the United States of America. He lived in Cambridge with his wife Emily and an infant son, Andrew.

Izsak pioneered in the development of both theoretical and practical aspects of the application of satellite data to geodesy. He directed the writing of a complex tesseral harmonics programme, which served as a powerful tool in his investigation of geodesy. From it he made determinations of the gravitational potential of the Earth. These results are the best representation so far of the Earth's potential.

Izsak also applied himself to the problem of refining the determinations of the positions of the Observatory's twelve Baker-Nunn camera stations for tracking satellites. In a dynamic approach, he used the Observatory's differential orbit improvement programme to obtain residuals in satellite position, and then analysed these residuals in his own tesseral harmonics programme to determine changes in station co-ordinates and the tesseral harmonics of the geopotential. These latter quantities are strongly correlated, and one cannot solve for one without solving for the other. Shortly before his death, Izsak directed the production of a new computer programme to combine the data from Dr. George Veis's geometric approach with that of his own dynamic approach. This has the effect of reducing the correlation of station positions and the tesseral harmonics. These investigations have shown that the geometric and dynamic methods agree well and have produced the most accurate global measurements of points on the Earth: the locations of the stations are all now known to within a few tens of metres, and those with the best determinations to within 10–20 metres. At the beginning of the programme, the corresponding precision was about 100 metres.

As a by-product of these undertakings, Izsak developed techniques for making numerical and analytical calculations using electronic computers. These programmes, which involve problems in celestial mechanics and have significant implications for interplanetary navigation, carry out algebraic operations that would take a life-time to do by hand.

The geodetic work in which Izsak played such a fundamental part will culminate in the publication of the Smithsonian Standard Earth, a concept he and others initiated. That model, which is expected to be the most accurate representation of these features yet available, will incorporate the results of his investigations of the geopotential and of the station co-ordinates.

Izsak wrote a number of scientific papers, including analyses of satellite orbits, a determination of the ellipticity of the Earth's equator, a second-order solution of Vinti's dynamical problem, and various notes on the mechanization of the tedious algebra of celestial mechanics.

Izsak was a warm, charming, witty, gentle person. He gained not only the deep respect but also the spontaneous affection of his colleagues. His association with them was one of mutual inspiration.

### Dr. R. F. Farquharson, M.B.E.

DR. R. F. FARQUHARSON died suddenly on June 1 at the age of sixty-eight while attending a meeting of the Medical Research Council in Ottawa.

With his death, Canada has lost the pre-eminent figure of its medical profession. To his work as teacher, research worker, consultant and statesman he brought a fine mind and a great heart. That he cared for people was obvious and everyone felt that his wise judgment was always available to them, as indeed it was. He gave the impression that he was prepared to be generous with his unusual talents, and this was coupled with an equally unusual ability to put them to work.

Early in his career it was apparent that he was a man who could accept responsibility, and over the years it was given to him to a degree that will not be seen again. For almost twenty years his advice was called for in connexion with almost every new medical enterprise. Both professional and lay organizations sought his counsel at their inception and some were fortunate enough to be able to continue to count him as one of their officers. Equally deftly he helped other and older groups who were in trouble and who, as they searched for new courses, needed his wisdom and the backing of his moral authority. It was the good fortune of the Royal College of Physicians and Surgeons of Canada to have him as its president in the crucial post-war years 1945–47, when the entire structure of the College was altered so that it could accept its responsibilities to the country for medicine at the specialist and consultant level. He presided at the transformation in 1960 of the Division of Medical Research, National Research Council, into the virtually autonomous Medical Research Council. During the Second World War he was consultant in medicine to the Director of Medical Services of the Royal Canadian Air Force. Immediately after the War he worked in association with the Director-General of Treatment Services, Department of Veterans' Affairs, and had much to do with the high standard of patient care which was evolved in association with the medical schools. From 1949 until 1962 he was a member of the Defence Research Board. During the discharge of these and innumerable other duties he was held in high esteem as a teacher. He was a brilliant consulting physician who remained to the end quietly and privately surprised that others did not have the skill at the bedside which was his.

It was natural that many honours should come his way. These he carried as lightly and with as little sense of self-importance as he carried the many secrets which were shared with him. In 1946 he was made a member of the Order of the British Empire, and in 1949 came the first of eight honorary degrees. He was elected a Fellow of the Royal Society of Canada in 1960. The clinical investigation unit in his own hospital has carried his name

for some years. A new science building in York University (Canada) will shortly bear it.

Dr. Farquharson is survived by his wife and two daughters.

G. M. BROWN

#### Prof. H. B. Gilliland

PROF. H. B. GILLILAND died on June 23 in Pietermaritzburg, at the age of fifty-four. From 1935 until 1954 he was a member of the staff in the Department of Botany, University of the Witwatersrand. During the Second World War he served in North Africa, working his way from private to major. From 1955 until

1965 he was professor of botany at the University of Singapore.

During 1964 Prof. Gilliland served as acting vice-chancellor of the University of Singapore. He was created professor emeritus in June 1965. Early in 1965 he took up the post of senior lecturer in botany in the University of Natal, Pietermaritzburg.

Prof. Gilliland was well known for his investigations in taxonomy and ecology, having published important contributions to these subjects both in Africa and in Singapore. He leaves a widow, a son and a daughter. His passing is greatly regretted by a wide circle of colleagues and old students.

J. F. V. PHILLIPS

## NEWS and VIEWS

### Chairman of the Social Science Research Council

IN a written reply to a question in the House of Commons on August 5, Mr. Anthony Crosland, the Secretary of State for Education and Science, announced that the Government had accepted in principle the recommendation of the Heyworth Committee to establish a Social Science Research Council. Mr. Crosland said that an Order in Council was being prepared, specifying the objects of the new body and declaring it to be a Research Council for the purposes of the Science and Technology Act 1965; the draft would be laid before Parliament, in accordance with Section 1 (4) of the Act, after the new Council had been established by Royal Charter. Mr. Crosland also stated that Dr. M. Young had been appointed chairman of the new Research Council. [See also *Nature*, 207, 559, 576; 1965.]

#### Dr. M. Young

DR. M. YOUNG has been a Fellow of Churchill College, Cambridge, since 1961, and director of the Institute of Community Studies since 1953. He was born in 1915 and was educated at Dartington Hall School and at the University of London. Later he was called to the Bar at Gray's Inn. Dr. Young was director of Political and Economic Planning from 1941 until 1945, and secretary of the Research Department of the Labour Party from 1945 until 1951. In 1956 Dr. Young became chairman of the Consumers' Association, and in 1959 he assumed the chairmanship of the Advisory Centre for Education. He has been a member of the Central Advisory Council for Education since 1963. Dr. Young is the author of *Family and Kinship in East London* (with Peter Willmott) (1957), *The Rise of the Meritocracy* (1959), and *Family and Class in a London Suburb* (with Peter Willmott) (1960).

### Natural Environment Research Council

MR. D. J. MACLEAN has been seconded from the Road Research Laboratory to the Natural Environment Research Council as a deputy chief scientific officer. As the senior officer (scientific) under the secretary of the council, Mr. Maclean will be responsible mainly for matters of scientific policy and for scientific programmes and for the Council's research grants and training awards. Until his secondment, Mr. Maclean was deputy director of the Materials and Construction Division of the Road Research Laboratory, Ministry of Transport, at Harmondsworth. He is best known for his work on soil mechanics and was largely responsible for the very successful book on soil mechanics for road engineers which was published by the Road Research Laboratory in 1951.

### Applied Physical Sciences in the University of Reading: Prof. P. B. Fellgett

DR. P. B. FELLGETT, head of the Astronomical Instrumentation Division of the Royal Observatory, Edinburgh,

has been appointed to a professorship in applied physical sciences in the University of Reading. Dr. Fellgett's first experience of research was towards the end of the Second World War, when he was a member of a group dealing with infra-red problems, under the leadership of Dr. (now Sir Gordon) G. B. M. Sutherland, in the Department of Colloid Science, Cambridge. Experience gained there stood him in good stead when in 1947 he became a research student at the Cambridge Observatories, where he obtained a Ph.D. for work on infra-red magnitudes of stars and the theory of ultimate sensitivity of radiation detectors. His thesis included a proposal for, and theoretical discussion of, an interference spectrometer of original design. He spent 1951-52 at the Lick Observatory and then returned to Cambridge, to follow up the ideas developed in his thesis by constructing a multi-channel interference spectrometer for use on stellar spectra in the near infra-red. In addition, with Linfoot, he applied information theory to the evaluation of optical images. In 1955 he joined the Cambridge Observatories staff as a senior observer. About this time he became convinced of the importance of using modern machine methods for the measurement of astronomical photographs taken with Schmidt telescopes, where traditional methods are much too slow to extract all the recorded information. He investigated the problems associated with designing a suitable machine, processing its output, and storing in a readily accessible form the large quantities of numerical data that would be produced. In 1959 he became a principal scientific officer at the Royal Observatory, Edinburgh, and there has taken a leading part in the development of such a machine (*Galaxy*), now under construction by Ferranti. He has also built up a strong electronics group at Edinburgh, has been responsible for elaborate control equipment for the new twin 18-in. telescopes, and has converted most of the Royal Observatory's measuring equipment, so as to give digital outputs suitable for immediate processing by an electronic computer. Dr. Fellgett has always been an enthusiastic advocate of the use of the most advanced optical and electronic techniques in observational astronomy, and an outspoken critic of those reluctant to depart from traditional methods and conventional instrumental design.

### Engineering Production at the Bradford Institute of Technology: Prof. R. C. Brewer

MR. R. C. BREWER, senior lecturer in the Production Engineering and Management Studies Section of the Department of Mechanical Engineering, Imperial College of Science and Technology, has been appointed to the newly established chair of engineering production at the Bradford Institute of Technology (proposed University of Bradford). Mr. Brewer was, for some nine years, lecturer, and later senior lecturer, at the Royal College of Advanced Technology, Salford. His research there was mainly concerned with the fundamentals of the machining

processes and the development of refractory oxides as tool materials. He is a British member of the International Institution for Production Research (C.I.R.P.) and is a United Kingdom member of the C.I.R.P./O.E.C.D., Co-operative Research Programme in Machining, for which he is chairman of the Statistics Sub-Group and secretary of the Surface Finish Sub-Group. In addition to research papers and *Reports of the Machine Tool Laboratory, Imperial College*, Mr. Brewer has published the following books: *The Numerical Control of Machine Tools* (1958), and *Manufacturing Properties of Materials* (1963). At Imperial College Mr. Brewer has been responsible for teaching and research of manufacturing processes. The chair in engineering production at Bradford has been established with the aim of applying mechanical engineering to production, as distinct from industrial or management aspects of production which are studied at the Institute's Management Centre. Mr. Brewer's responsibilities will include developing teaching and research in this field.

#### Polymer Chemistry In McGill University, Montreal:

Prof. L. E. St. Pierre

DR. LEON E. ST. PIERRE, manager of the Polymer and Interface Studies Section, General Electric Research Laboratory, Schenectady, New York, has been appointed the first professor of polymer chemistry in McGill University, Montreal, which is situated in the Otto Maas Chemistry Building, a new laboratory on the campus at the corner of Sherbrooke and University Streets. The new laboratory will pursue fundamental research on the chemistry of polymers and expand opportunities for graduate students to train themselves in this specialized field. Industries based on polymers, notably in textiles, plastics and elastomers, will thus have an increased pool of already specialized talent from which to recruit staff, in addition to the benefit of additional knowledge of the chemical processes and mechanisms of polymerization. Dr. St. Pierre is a native of Edmonton and was educated at the University of Alberta, where he graduated *magna cum laude*, and the University of Notre Dame, Notre Dame, Indiana, where he earned his Ph.D. degree in 1954. Since that time he has conducted research on various aspects of polymer chemistry at the General Electric Research Laboratory, and he has published numerous scientific articles in professional journals.

The new laboratory occupies almost all of the fourth floor of the two blocks forming the east wing of the Otto Maas Chemistry Building, and in addition to normal service and equipment, it will have its own constant-temperature and instrument rooms. Although organized as a separate, discrete unit, it will be situated close to those specialized laboratories of particular use in polymer chemistry: radiochemistry, mass spectrometers, ultra-centrifuge and electrophoresis laboratories. Nuclear magnetic resonance, ultra-violet and infra-red equipment are also situated nearby. The new chemistry building, although not yet formally opened, was occupied by the end of June, and all parts, including the polymer laboratory, are expected to be working when classes commence in September. Twenty industries and associations, with an interest in polymer chemistry, have contributed to the capital costs and some operating expenses of the new Laboratory. In addition to its new research facilities, the Department of Chemistry, under Dr. C. B. Purves, chairman, has existing research laboratories of inorganic, physical and organic chemistry, radiochemistry and pulp and paper chemistry, the last-mentioned being also an integral part of the Pulp and Paper Research Institute of Canada.

#### Organic Chemistry In the University of Reading:

Prof. D. Bryce-Smith

DR. D. BRYCE-SMITH has been appointed to the newly established chair of organic chemistry in the University

of Reading. He was at Bancroft's School, Essex and afterwards studied at the South-west Essex Technical College, the Sir John Cass Technical Institute and the West Ham Municipal College. In 1945 he became a research assistant with Powell Duffryn Research, Ltd. and from 1946 until 1948 was a research chemist for Dufaycolour, Ltd. For the following three years he carried out research for a Ph.D. at Bedford College, University of London. From 1951 until 1955 he held an Imperial Chemical Industries postdoctoral research fellowship at King's College, London, and in the latter year was appointed assistant lecturer at the same College. He took up his post as lecturer in the University of Reading in 1956, being promoted reader in 1963. He was awarded a D.Sc. of the University of London in 1960. Dr. Bryce-Smith's main research interests are in the development of new synthetic methods in organic chemistry and in the study of reaction mechanisms; his principal fields of work have been the photochemistry of organic compounds and organometallic compounds. Other topics of his work falling outside these two main fields include catalytic reactions of acetylenes on noble metals, the chemistry of tropylium salts, syntheses of carboxylic acid anhydrides and *p*-quinones, and the reactions of silver benzoate-halogen complexes with aromatic compounds.

#### Physical and Inorganic Chemistry In the Chelsea College of Science and Technology: Prof. H. J. V. Tyrrell

DR. H. J. V. TYRRELL has been appointed to the chair of physical and inorganic chemistry at the Chelsea College of Science and Technology. Dr. Tyrrell was educated at Newport (Monmouthshire) High School, and at Jesus College, Oxford, which he entered in 1938 as a Welsh Foundation Scholar in chemistry. After graduating in 1942 with honours in chemistry, he held several industrial appointments before going to the University of Sheffield as assistant lecturer in chemistry in 1947. His appointment coincided with the beginning of the post-war expansion of the Department, and he has had long experience of the problems associated with such developments. During his period in industry, Dr. Tyrrell had been concerned mainly with the electrochemical production of metal powders, and with corrosion problems, and it was experience in the latter field which led him to begin an investigation of electrolytic thermocouples at Sheffield. This led, in turn, to a general interest in non-isothermal systems, and in the thermodynamics of irreversible processes, reflected in his monograph on "Diffusion and Heat Flow in Liquids", published in 1961. He has also been interested in the thermodynamics of complex equilibria in solution and in spectroscopic topics. In 1963 he was awarded the degree of D.Sc. by the University of Oxford, and has recently become reader in physical chemistry in the University of Sheffield. For many years he has been closely associated with the work of the Chemical Society, first as local representative for Sheffield and then as a member of the Publications Committee. Dr. Tyrrell's experience in industry and in the academic field will be valuable in his new appointment to a College which is strongly orientated towards technology and which will undergo many changes during the next few years.

#### The Overseas Development Institute

THE annual report for the year April 1964-March 1965 of the Overseas Development Institute records the firm establishment of the Institute as a centre dealing with most aspects of aid and development (Pp. 24. London: The Overseas Development Institute, Ltd., 1965). A large two-day conference on the economic and social development work of the United Nations was sponsored by the Institute. It is recorded that the library has collected about 2,500 books and pamphlets and receives more than 100 periodicals regularly. The basis of all the work of

the Institute remains its study programme, and the year was the last full year in which financial help will be received from the Nuffield Foundation for studies of development problems. Five studies have been published dealing with British aid, one with German aid, another with Japanese aid, and a third on the Jeanneney Report dealing with French aid, as well as others dealing with India at 'mid-passage', aid to Africa, aid to the West Indies and with assistance rendered 'Not by Governments Alone'. Other studies during the year have included a special examination of private investment and one of British aid to agriculture. Projected investigations include one of recipients, another of donors, an annual survey of Britain's aid problem and others dealing with trade and with the private sectors. Financed by a special grant from the Nuffield Foundation, the first three of the Institute's Nuffield Fellows went to Uganda, Kenya and Tanganyika in the summer of 1963, and three more Fellows were sent out in 1964. A further and increased grant from the Nuffield Foundation has made it possible to appoint six Fellows this year for 1965-67 and six next year for 1966-68. The Governments which will employ the Fellows are asking for twenty new Fellows this year, and applications have been received from about fifty candidates in the United Kingdom.

#### Analysis and Planning of Management

In an article reprinted from *Personnel Management*, June 1965, Mr. M. Hull argues that the analysis and planning of manpower have been neglected both at the level of the firm and over the economy as a whole. After describing the technical potential of the computer in this field, he points out that standardized codings of labour are required for educational and occupational purposes. He suggests that a statistical manpower grid, derived from the records of firms with mechanized payrolls, ideally coding on similar lines, could provide valuable information on the utilization of manpower, including correlations between industrial usefulness and academic qualifications. Such a system, he considers, is both technically and economically possible and would enable the supply of labour at all levels to be related better to needs.

#### Abbé Lazzaro Spallanzani

It is just 200 years since the Abbé Lazzaro Spallanzani (1729-99) anticipated Pasteur's work and that of John Tyndall when he banished the idea of spontaneous regeneration of living matter, a contribution soon forgotten since it was beyond the comprehension of the scientists of his day. Philosophers such as Diderot had directed attention to this question, discussing in his *Interpretation of Nature* whether living matter could combine with living matter, whether "the energy of a living molecule could vary by itself or according to the dead or living matter with which it united". The two priests Needham and Spallanzani took up the theme—after Needham had studied "very small organisms" with Buffon. Needham visualized a productive or vegetative force charged with the formation of organic matter. Spallanzani examined Needham's method of enclosing putrescible matter in vessels warmed to produce animalcules (as he thought), and the controversy between the two opened. Spallanzani realized that Needham had not used a sufficiently high temperature to destroy bacteria or "seeds" of living matter as he called them. By avoiding porous cork or stoppers on vessels, and using sealed vessels maintained for an hour in boiling water, Spallanzani found on opening them that "not the slightest trace of animalcules remained, though I had examined with a microscope the infusions from 19 different vessels". Despite his accurate observations and the controlled conditions which he used to verify his results, Spallanzani was little appreciated, and the full significance of his work

had to await the work of Pasteur and of Nicolas Appert. Even the vigorous attack on Needham by Voltaire, who was ever ready to cross a nib to deride "the Irish Jesuit" as he called him, did not help recognition of Spallanzani's work. Voltaire jested at a race of so-called eels which had their origin in gravy from boiled mutton; at philosophers who claimed there is no germ, that all is regenerated by a vital force of nature. He derided "clever scientists taken in by a Jesuit", although Needham had been "so triumphantly refuted by M. Spallanzani".

#### Museum of Comparative Zoology, Harvard University

THE annual report of the Museum of Comparative Zoology at Harvard University directs attention to the considerable expansion which has taken place during 1963-64 both in teaching and research activities (Pp. 40. Cambridge, Mass.: Museum of Comparative Zoology, Harvard University, 1965). As in previous years, many members of staff were invited to give lectures at congresses, conferences and seminars. Field research included expeditions to East Africa, Anatolia, Turkey, and an Indian Ocean investigation aboard the R/V *Anton Brum*. Research centred around evolutionary biology and such problems as: How did the enormous diversity of life on this world evolve?; What are the mechanisms, the causal determinants and the environmental conditions? Recognizing that it is as true to-day as it was 200 years ago that sound taxonomy is the indispensable basis of all research in zoology and botany, at least part of the time of the staff is devoted to basic taxonomic researches. In this connexion Prof. F. M. Carpenter has nearly completed his insect volume for the *Treatise on Invertebrate Paleontology*, and Dr. B. W. Evans has completed his revision of the genus *Rhabdopyris*, probably the most generalized group of the large sub-family *Epyrinae*.

#### The University Museum, Oxford

ON May 1, 1964, the Delegacy for the University Museum, established in 1853, ceased to exist, its place being taken by the Delegacy for the Science Area. Fuller responsibility for the Museum proper is now vested in the Committee for the Scientific Collections. In view of serious overcrowding and the need to provide for the proper display and expansion of the collections, the suggestion in the Holford Report that new accommodation for the Pitt-Rivers Museum should be provided, in association with the Institute of Social Anthropology and the Research Laboratory for Archaeology, was welcomed. For the immediate future, a modern, artificially-lit exhibition gallery, of approximately 600 square feet, has been built immediately inside the Pitt-Rivers Museum court at the foot of the main entrance stairs from the University Museum (Seventy-sixth Report of the Delegates of the University Museum and First Report of the Delegates of the Science Area. (For the year ending July 31, 1964.) Supplement No. 4 to the *University Gazette*, March 1965. Pp. 133. Oxford: The University. 10s.).

#### Catalogue of Bronze Implements

THE card catalogue of British bronze implements, started by the British Association in 1913, has since 1955 been on loan to the Department of European Archaeology at Oxford, where it has been brought up to date under the supervision of Prof. C. F. C. Hawkes. Early in October this year it will be returned to the British Museum and installed in the new Students' Room of the Sub-department of Prehistory and Roman Britain.

#### Diamonds In Metalworking

THE use of diamond tooling in machining very hard materials has been known for many years. The problem of sintered tungsten carbide in this connexion was faced during the 1920's and only diamond was found hard enough to solve it satisfactorily. From this inception

came the idea of research into design of suitable diamond tools, embodying stones of different grades and sizes, to machine many other hard materials from ceramics to concrete. But to-day diamond has many industrial uses where reliance solely on the hardness of the workpiece is the chief criterion of its efficiency in metalworking. For example, it is frequently used in machining soft materials such as copper or brass, where a particularly high degree of mirror finish is required; it is specified on long automated production runs to overcome time lost in replacing worn tools, thus saving cost of idle plant; in deep grinding, the use of suitable diamond tools can achieve a very good finish after large quantities of stock in a single pass have been removed. Diamonds now used in metalworking fall roughly into five groups, in descending order of stone or particle size, according to a recent publication *Diamonds in Metalworking* (Pp. 20. London: Industrial Diamond Information Bureau, June 1965). These groups comprise: (1) large stones, which are almost of gem quality except for imperfect colouring, used for wire-drawing dies; (2) slightly smaller stones, again near gem quality, incorporated into single-point tools for turning or dressing; (3) very small stones applied in clusters to dressing tools, this design to meet requirements of less skilled and experienced operators; (4) the well-known diamond grit, graded by sieves into a wide range of particle sizes, available in both natural and synthetic form, and conventionally bonded to surfaces of grinding wheels or profiling rollers; (5) diamond powder of fineness outside normal sieve range, which is mixed with light oils to form the basis of extremely efficient polishing paste. This well-illustrated brochure conveys adequately the information it seeks to impart on the wider use of industrial diamond. In fact, wherever speed must be coupled with precision engineering, the impression is that diamond tooling will probably provide the most frequent answer to the problem.

#### Summer School in Crystallography in Pyongyang

A SUMMER school in crystallography was held in Pyongyang, North Korea, during July 5-16. The arrangements were made under the auspices of the Association of Democratic Scientists of Korea. Some twenty persons took the course, most of whom were students of physics in their fourth year at the Kim Il Sung University of Pyongyang. The text of the lectures had been submitted in advance by Dr. W. A. Wooster, and the lectures were delivered in Korean by Assistant-Prof. Jung Kuen. A suitable room for the course was provided in the centre of the city in the Library of the Academy of Sciences. The course consisted of twenty lectures in X-ray crystallography, each lecture being followed by a 2-h period of practical exercises by the students. The emphasis in the course was on these practical exercises in the interpretation of all kinds of single-crystal data, and the lectures were written mainly as an introduction to the exercises. The students were remarkably diligent and seemed interested in their work. Their previous studies had not included much single-crystal work. Very few members of the course knew English, but with the help of interpreters this difficulty was largely overcome. Dr. Nora Wooster assisted with the practical demonstrations.

#### Geology of the Wealden District

THE eighteen handbooks in the *British Regional Geology* series, designed to provide a simple but authoritative account of the geology of various parts of England, Wales and Scotland, have proved to be among the most popular publications of the Geological Survey and Museum since they were first published in 1935, and they have all passed through two or more editions. Thirty years, however, is a long time for a work to remain in the same format, and the fourth edition of the handbook to the Wealden district has had a face lift (Department of

Scientific and Industrial Research. Geological Survey and Museum. *British Regional Geology—The Wealden District*. Fourth edition (based on previous editions by the late F. H. Edmunds). By R. W. Gallois. Pp. xii+101+13 plates. London: H.M.S.O., 1965. 6s. net). The guide covers the geology of Kent, Sussex and parts of Surrey and Hampshire. It successfully relates the geology of the region in a readable manner which can be understood by students, naturalists, and the enquiring layman; and with the aid of excellent photographs of the countryside and of typical fossils it should do much to evoke an intelligent tourist's interest in the local scenery. Unfortunately it does not contain an electron-microscope photograph of the marvellously minute coccoliths which make up the Chalk cliffs portrayed on the front cover, representations of which peculiarly English organisms have found their way into foreign text-books but not yet into British ones. At 6s. the handbook is most reasonably priced, and it is to be hoped that it will shortly be followed by similar attractively produced volumes covering the rest of Britain.

#### E-route International Highway Network

PLANNED as long ago as 1950 at a meeting of various Ministers of Transport in Geneva, a network of twenty-six main international routes, each with the designation 'E' for Europe, plus a number, was mapped out, including branch and link roads connecting all important cities to the system. Already 4,600 miles of this system have been completed, and by 1970 it is anticipated that about 10,000 miles will have been achieved, involving the six Common Market countries together with Austria, Britain and Switzerland, and others to follow. This enormous project involves not only many spectacular bridges already open or under construction, but also the two longest automobile tunnels in the world, the Great St. Bernard Tunnel at the Swiss-Italian border on route E2 between Lausanne and Turin (completed in 1964) and the 7.2-mile Mont Blanc tunnel linking France and Italy, recently opened. A striking article by Jack Long entitled simply "E" and published in *The Lamp* by the Standard Oil Company, New Jersey (New York, N.Y. 10020; 47, No. 1; April 1965), gives some interesting details of this project and includes an excellent map depicting many of the proposed E routes. Part of the scheme involves the Channel Tunnel (if and when constructed) with the E5 linking London, Budapest, Belgrade, Istanbul and Ankara, and E2 the direct route from London to Milan and Bologna and beyond, while E1, presumably involving a cross-Channel ferry-service via Southampton, is routed through Paris to Florence, Rome, Naples and Palermo. Other prominent routes are E4, linking ultimately Lisbon, Madrid, Barcelona, Basle, Frankfurt, Hanover, Hamburg, Copenhagen, Stockholm and Helsinki; E8 from Amsterdam via Berlin, Warsaw to Moscow; E12, from Paris via Frankfurt, Prague and Warsaw to Leningrad; and E3 from Lisbon to San Sebastian, Paris, Brussels, Hanover, Hamburg and so to Stockholm. It is concluded that the forces drawing Europeans together are stronger than those separating them, and one unifying force is certainly this 'E' road system, not only as it may ultimately be realized, but also as the links in the chainwork are slowly but progressively forged.

#### System-built Houses

IN recent years the development of new techniques and machines has made available better and more economical supplies of such everyday commodities as food, clothes, furniture and many other necessities of modern life; in comparison, the building industry in Britain has in many respects remained strangely conservative. It still tends to cling to traditional materials and methods, and speed of construction is seldom achieved on the same scale as, for example, in Scandinavian countries and the United

States, where what is known as 'system building' has been successfully adopted for many years past. It is abundantly clear, however, that with the present and seemingly endless shortage of houses to meet an increasing population and higher standards of living, the next few years will witness revolutionary changes in the building industry brought about by the adoption of factory-made units, at least for certain types of housing. In a recent issue of *Ciba Technical Notes*, entitled "Ciba Glues in System-Built Houses" (Pp. 8. Duxford, Cambridge: Ciba (A.R.L.), Ltd., April 1965), a brief illustrated account of the 'system' in operation is presented. Among the advantages claimed for this form of prefabrication, apart from the speed of construction, are: a smaller labour force is needed on site; building sites, being notoriously unpleasant, especially in bad weather, are not conducive to good work, whereas inside a factory components are carefully fashioned regardless of weather, and supervision of working processes can be more strictly exercised; such units can more readily incorporate modern materials to give the building good weathering and thermal qualities; compared with traditional walls made of bricks and mortar, many units are light in weight, economies thereby being made in cost of foundations; plumbing, heating and ventilation can be standardized using well-conceived and tested designs; finally, overall costs are reduced because production can be planned in detail, no time is lost owing to bad weather, and seasonal employment of building workers is largely avoided. The Housing Development and Construction Co., Ltd., Stratford upon Avon, has developed such a system, suitable for a wide range of buildings: houses, schools, hospitals, old people's houses, etc., of which brief details are given, including use of Ciba wood glues, 'Aerodux' and 'Aerolite', which are fundamental to the strength and durability of certain units. It is, however, stated that "... factory-made houses are generally suited to estates, and it is often uneconomical to erect single houses on sites far removed from the factory."

### Rural England

THE Sheffield and Peak District Branch of the Council for the Preservation of Rural England maintains constant vigil on behalf of all who may be affected. In the annual report for 1965 many examples are given of how the vigour of the Branch and its officers has resisted encroachment on surrounding amenities (Pp. 28. Sheffield: Council for the Preservation of Rural England, Sheffield and Peak District Branch, 1965). The report also describes the recent gift to the National Trust, by two local donors, of some 8 acres under and including a part of Baslow Edge at Curbar Gap which provides magnificent views over the Derwent Valley. Also included is a reference to the work of the Council for the Conservation of Sheffield Antiquities in restoring the Abbeydale Works. This is the last remaining place where steel-making and forging processes of the 1750's can be studied in their original forms. Their scenic setting is attractive. An appeal has already brought in more than £30,000, and the completed project should add much interest to a city which has lost many historic features.

### World Health Organization Publications

Among the *Technical Report Series* issued recently by the World Health Organization, No. 300 is of special interest in that it discusses *The Effects of Labour on the Fetus and Newborn* (Pp. 32. Geneva: World Health Organization; London: H.M.S.O., 1965. 2 Sw. France; 3s. 6d.). Pre-natal mortality has, in many countries, remained almost stationary for the past ten years at the level of about 30 per 1,000 births—a considerable reduction since the beginning of the present century. Experience, however, suggests that it could be reduced still further. Apart from the children who die, many survive with such permanent handicaps as spasticity or mental deficiency

(attributable to the effects of labour). This report examines the complex factors involved in childbirth, the ways in which the process of labour may be upset to the detriment of the infant, defects in intra-uterine and postpartum environment which affect the child's capacity to survive and its future health. Perinatal infection is examined in relation to labour and caution is expressed about the use of drugs and other forms of therapy before and during labour. Recommendations for research are made and the report pleads for the provision of qualified and adequately trained personnel to care for the mother and child.

Among other publications recently published are a useful 1947-1964 *Catalogue of World Health Organization Publications* (Pp. 114), and the third report of the World Health Organization Expert Committee on Bilharziasis (*Technical Report Series*, No. 299. Pp. 56. 3 Sw. France; 5s.). The latter describes, among other features, the planning in detail of a bilharziasis control programme. Another valuable publication entitled *Snail Control in the Prevention of Bilharziasis*, 30s., discusses the chemical composition and relative merits of the newer molluscicides now in use or on trial together with methods of applying them and the risks of some of them to the operators and to agriculture. Types of cercarial larvae that may be encountered are described, so that they can be differentiated from the cercariae which affect man. Studies of man-made and natural snail habitats are recorded together with the methods and apparatus used for collecting snails. This publication should interest all biologists and should be useful to veterinarians, who have to control diseases of farm stock, such as fascioliasis.

### Vascular Plants of South Georgia

THE only previous major work on the botany of South Georgia, a comparatively small and remote but nevertheless interesting island of the South Atlantic, was written more than a half-century ago by Carl Skottsberg (1912). It is therefore particularly gratifying to note how much work has been done by S. W. Greene (*Vascular Flora of South Georgia*. Pp. 58+24 maps and 6 plates. London: British Antarctic Survey, 1964. 32s. 6d.) not only in bringing the systematic botany of the vascular plants of the island up to date, but also in dealing with topics of historical, geological and ecological importance. In this publication the author has set out to provide students of the area, as well as intending scientific visitors, with a concise and compact account of its botany. He gives most useful, if rather brief, accounts of the topography and geology, and also the various ecological communities relevant to the vascular plants. A very extensive and interesting section is devoted to the history of botanical exploration of the island from its earliest visit by Cook in 1775 up to the time immediately prior to this publication. In this latter section, not only is each individual visit to the island recorded, but also the extent of the collections made and their present location—information most valuable to students of the flora of Antarctica. In addition to these individual entries, tables are provided showing the location in the major world herbaria of all the plants known from the island. The systematic section of the work is very concise with clear and positive descriptions of the plants, although it is a great pity that, of the 24 taxa regarded by the author as native to the island, only seven have been illustrated in any form. There can be no doubt that Dr. Greene's volume will be regarded as one of the most valuable on the flora of the island, and it is hoped that at some future date he will supplement this with a similar systematic treatment of the lower plants, particularly the Bryophyta, in which South Georgia is very rich.

### A New Species of Catfish from the Zambesi

IN 1955 a strange clariid was taken from the Zambesi River, about 15 miles above the Victoria Falls, by Mr.

T. E. Davidson, then warden of the Wankie National Park. The specimen was put aside while attempts were made to discover others, but although several collections have since been made in the Zambezi and its tributaries, none has been found. With the aid of photographs, this unique specimen has been discussed in considerable detail by R. A. Jubb, Freshwater Fish Section, Albany Museum, Grahamstown, with Dr. P. H. Greenwood, whose papers have contributed much to knowledge of the Clariidae and the comparative anatomy of their suprabranchial organs (*Ann. Mag. Nat. Hist.*, 7, No. 79; 1964). As a result of this discussion, it has been concluded that this Zambezi clariid is a new species for which provision should be made in the genus *Clariallabes*, Boulenger, 1900. The genotype *Clariallabes melas* has the dorsal and anal fins united with the caudal, a feature which is also evident in the type *Cl. petricola*, Greenwood, 1956. This feature, however, is not consistent, as Greenwood now has specimens of *Cl. petricola* which have a distinct gap between the caudal, and the dorsal and anal fins.

### Lady Tata Memorial Fund Awards

THE Trustees of the Lady Tata Memorial Fund for research in leukaemia and allied disorders have made the following awards for the academic year 1965-66: *Fellowships*, Dr. V. Buonassisi (Rome); Dr. M. Matsuyama (Aichi Cancer Center, Nagoya, Japan); *Scholarships*, Dr. G. Corneo (Laboratory of Molecular Biopathology, Milan); Dr. D. Quaglino (Institute of Medical Pathology, Modena); Dr. G. Tridante (Division of Experimental Cancer, Bari); *Expenses Grants*, Dr. A. Agostoni (Medical Clinic, Milan); Dr. J. de Maeyer (Department of Virology, Louvain); Dr. F. Squartini (Institute of Pathological Anatomy and Biology, Perugia).

### University and College News: Birmingham

THE following appointments have been made: *Senior Lectureships*, H. F. Downton (mathematical statistics). *Lectureships*, Dr. N. T. Bailey (mining and minerals engineering); J. M. Joffe (psychology); A. Trainor (materials science); Dr. A. E. Williams (microbiology); Dr. P. M. H. Raab (physiology). *Research Fellowships*, Dr. J. Baugh and Dr. D. G. Ryan (physics); T. Pratt (electronic and electrical engineering).

### Newcastle upon Tyne

THE following lecturers have been appointed: J. D. Simmett (experimental pathology in the Department of Pathology); Dr. D. T. Edmonds (hydraulics and hydrology in the Department of Civil Engineering).

### Salford

Dr. J. G. HATHCOTE has been appointed reader in biochemistry at the Salford Royal College of Advanced Technology.

### Swansea

THE following lecturers have been appointed: T. H. Walton (pure mathematics); Dr. J. W. Barnes (geology).

### Announcements

LORD MURRAY OF NEWHAVEN, chancellor of the University of Southampton, has been appointed to the Board of Trustees of the Wellcome Trust.

A SYMPOSIUM on "Elastohydrodynamic Lubrication", arranged by the Institution of Mechanical Engineers, will be held in Leeds during September 20-22. Further information can be obtained from H. Umpleby, Institution of Mechanical Engineers, 1 Birdcage Walk, London, S.W.1.

THE thirteenth symposium on "Vertebrate Palaeontology and Comparative Anatomy" will be held at Royal Holloway College, Englefield Green, during September 20-22. Further information can be obtained from P. M. Butler, Department of Zoology, Royal Holloway College, Englefield Green, Surrey.

AN international conference on "Elementary Particles", organized by the Rutherford High Energy Laboratory, will be held in Oxford during September 19-25. Further information can be obtained from Mr. R. C. Pepperell, Scientific Conference Secretariat, Rutherford High Energy Laboratory, Chilton, Didcot, Berkshire.

THE third international symposium on "Natural Mammalian Hibernation" will be held in the University of Toronto during September 13-16. This will mark the opening of the Ramsay Wright Zoological Laboratories. Further information can be obtained from Dr. A. R. Dawe, Office of Naval Research Branch Office, 219 South Dearborn Street, Chicago, Illinois.

AN international conference on "Thermionic Electrical Power Generation", organized by the Institution of Electrical Engineers under the auspices of the European Nuclear Energy Agency of the Organization for Economic Co-operation and Development, will be held at the Institution of Electrical Engineers during September 20-24. Further information can be obtained from the Secretary, Institution of Electrical Engineers, Savoy Place, London, W.O.2.

## THE NIGHT SKY IN SEPTEMBER

All times are in Universal Time

MOON		CONJUNCTIONS WITH THE MOON	
New Moon	25d 03h	Venus	28d 07h, 8° S.
Full Moon	11d 00h	Mars	29d 01h, 2° S.
		Jupiter	18d 20h, 2° S.
		Saturn	10d 12h, 8° N.

### PLANETS

Times of Rising (R) and Setting (S) during the month

## PROF. J. L. W. THUDICHUM (1829–1901)

JOHN LEWIS WILLIAM THUDICHUM is regarded to-day as the father of neurochemistry. During 1865–82 he carried out a series of brilliant pioneer investigations on the analysis and characterization of brain tissue. This began the process of defining the nervous system in chemical terms—a scientific endeavour which has continued and is still gaining momentum to-day. Although Thudichum carried out virtually all his scientific work in London he was born in Büdingen, a small 'medieval' town in the old Grand Duchy of Hesse. It was here that after a recent colloquium in Mosbach, Baden, representatives of the Gesellschaft für Physiologische Chemie gathered to unveil a plaque on his birth-place (Fig. 1).

Fig. 1

Thudichum's family, distinguished in scholarly attainments, originated in the town of Marbach, the birthplace of the poet Schiller, and in this atmosphere he derived a great love for the classics. This latter expressed itself not only in his naming of the substances which he discovered but also in his non-scientific writing. Thudichum studied medicine at Heidelberg and later at Gießen where he was encouraged by his teacher, the great chemist Justus von Liebig, to develop a deep interest in the chemistry of natural substances.

Soon after graduation, Thudichum came to London where he married and settled for the rest of his life. Until his death he actively pursued the clinical practice of medicine, being a skilled otologist and rhinologist. He devised many surgical instruments and published a treatise on nasal polyps (which ran to several editions) and one on gall stones.

However, his interest in the application of chemistry to medicine steadily grew, he lectured in pathological chemistry at the old Grosvenor Place School of Medicine and then in 1865 he was appointed as lecturer in pathological chemistry in St. Thomas's Hospital, London. He also devoted himself to his chemical researches; urochrome, the principal colouring matter of the urine, was isolated in 1864, and he also made many important contributions to our knowledge of the carotenoids or 'luteins' as he called them.

These investigations, however, were probably not of such sustained importance as his work on the chemistry of the brain. These were carried out in his private laboratory and were supported by the Privy Council, the medical officer of which, Sir John Simon, quickly appreciated the value and brilliance of Thudichum's work. Sir John believed that eventually all diseases of the brain would be explained in chemical terminology and to do this it was first necessary to understand the chemistry of the normal brain. This in those days was remarkably far-sighted and is a line of reasoning not unfamiliar to many present-day neurochemists filling out applications for grants to support their work.

Thudichum continued his work on the brain during 1865–82, carrying out systematic analyses which resulted in the isolation of many new and important compounds, for example, sphingomyelin, cephalin, phrenasin, kersasin, sphingosine and cerebronic acid. Although in these days of chromatography we have become quite familiar with the rapid and easy separation of lipids, in the context of the times this was indeed a remarkable achievement. His work was published in a series of reports to the

Privy Council and in 1884 his classic work on the *Chemical Constitution of the Brain* appeared in English, followed by a revised edition in German.

On his retirement from active chemical work, Thudichum wrote two most unusual works: the *Spirit of Cookery* appeared in 1895 and a *Treatise on Wines* in 1896. This illustrates the great diversity and originality characteristic of the man. His ever active mind and spirit appeared tireless to his contemporaries; he invented, wrote poetry, painted, sang with a fine voice and, like so many scientists, had a deep love of music. This combined brilliance often proved too much for lesser mortals and evoked unjust criticisms of his work. Nevertheless, his contribution has stood the test of time and his pioneering work still continues to act as a lead and inspiration to present-day neurochemists.

H. DEBUCH

R. M. C. DAWSON

## SCIENCE IN PARLIAMENT

### Metric System

IN a written answer in the House of Commons on May 24, Mr. D. Jay, the President of the Board of Trade, stated that the Government was impressed with the case which had been put to it by the representatives of industry for the wider use in British industry of the metric system of weights and measures. Countries using that system now took more than half Britain's

exports and the total proportion of world trade conducted in terms of the metric unit would probably increase. Against that background the Government considered it desirable that British industries on a broadening front should adopt metric units, sector by sector, until that system became in time the primary system of weights and measures for Britain as a whole. The Government had therefore asked the British Standards Institution—and the Institution had agreed—to pay special attention

to the provision of metric standards, wherever possible internationally recognized, and to press on with this as speedily as possible. The Government would take this new commitment into account in determining the amount of future grants-in-aid to the Institution. It was also considering how best to encourage the educational work to familiarize future school generations and students in technological establishments with working in terms of metric units. The Government would also encourage a change to the metric system as and when this became practical for particular industries, by seeking to arrange that tenders for procurement by the Government and other Public Authorities should be in terms of metric specifications. The Government hoped that within ten years the greater part of Britain's industries would have effected the change and to this end it proposed to establish a small standing joint committee of representatives of Government departments and industry to facilitate the removal of obstacles and keep under constant review the progress which was being achieved.

In the House of Commons, on June 15, the Minister of Technology stated that his Department would give every possible assistance to the British Standards Institution through its research stations and advisory staff in preparing the new series of British Metric Standards foreshadowed by the President of the Board of Trade. The Ministry of Technology, through its research stations and the grant-aided research associations, was represented on more than a thousand committees of the British Standards Institution. The measures under discussion included production of a comprehensive manual of international metric units used in industry. In collaboration with the Central Office of Information, assistance had been given to the Publishers' Association to revise engineering text-books for the domestic and export markets.

#### Machine Tool Industry

In a statement in the House of Commons on June 14, Mr. F. Cousins, the Minister of Technology, said that his Department was engaged in a full study of the machine tool industry. He welcomed the undertakings given by manufacturers' representatives to press for action on increased capacity, on building up research and development and qualified staff, on increased specialization and elimination of wasteful duplication, and on development of British machines to replace some types that are imported. Similar important undertakings had been given about the improvement of deliveries, and the manufacturers had also agreed to initiate a review of the factoring of improved machine tools by British manufacturers. Mr. Cousins said that the Government would also play its part and, to assist the industry to develop and produce more of the most advanced and efficient types of machine tool, research and development contracts would be considerably increased. The National Research Development Corporation was already examining a number of projects and the new Act would enable it to make a greater contribution on terms which should find wider acceptance in industry. The Government was prepared to order pre-production models for approved new types, and the National Engineering Laboratory at East Kilbride would be built up to give further support in the research field: its expanded activities should yield ideas for development projects. The Laboratory would mount a major effort, supported by appropriate machine tool control engineering and user firms, on applying numerical controls to manufacturing process and using computers to assist design. His Department was negotiating for a suitable British-made powerful computer for this purpose.

Mr. Cousins emphasized that the machine tool industry was too fragmented and must be concentrated into stronger units which could better meet the needs of industry. The Machine Tool Trades Association had agreed that the industry itself must take the

lead in concentration and rationalization. One of his industrial advisers would direct particular attention to methods of promoting concentration and placing development contracts and pre-production orders to this end. His Department had also studied the serious difficulties created by the cyclical pattern of ordering machine tools, and a working party was studying the question of Government participation in financing building to stop its flat periods. The Government had also accepted the recommendation of the Machine Tool Economic Development Committee that machine tool holdings of Government establishments should be considered with the view of replacing older types with more modern machines when economically advantageous. It also accepted the recommendation that Government contracts should encourage advanced methods by stipulating the use of particular manufacturing techniques. Mr. Cousins referred to the important part that universities had to play in advancing machine tool technology: the Government had directed the attention of the University Grants Committee to the recommendation of the Economic Development Committee in this connexion. Mr. Cousins stated that he was setting up at his headquarters an expert machine tool unit the functions of which would include acting as a focal point for co-ordinating research and development in Government establishments with that in research associations, the National Research Development Council, universities and industry. This new unit would be developed to provide a technical advisory service to Government and public users of machine tools and, if desired, for private purchasers.

#### Greenland Fishing of Atlantic Salmon

In reply to a question from Lord Balfour of Inchrye in the House of Lords on July 5, regarding the Greenland fishing of Atlantic salmon, Lord Hughes, the Joint Parliamentary Under-Secretary of State for Scotland, said that the increase in exports of Atlantic salmon from Greenland from 2 metric tons in 1957 to 1,400 metric tons in 1964, mentioned by Lord Balfour, was quite correct. To that figure, however, had to be added the amount retained for consumption in Greenland itself, probably some hundreds of tons, but the total left out *grilse*, which were not reflected in the Greenland figures. As there was only one salmon river in West Greenland, it seemed that salmon caught off the coast must have bred elsewhere: and salmon tagged mostly as smolts in Britain and in other countries on either side of the Atlantic had been caught in this fishery.

Lord Hughes stated that of 64 salmon caught in Greenland up to May this year, just more than half had been tagged in the United Kingdom, but the information was still very scarce in some respects and insufficient for a final and reliable judgment. Partial information was to some extent reassuring. All the salmon caught in Greenland that had been tagged in Scottish waters came from half a dozen batches of smolts, totalling 38,000, and had been tagged between 1961 and 1963. Up to May 1965, 45 had been recaptured, but nearly all on their return to Scottish waters and only 13 off Greenland. It was not known, however, whether tagged salmon were easily recognized as such in the Greenland fishery and almost 90 per cent of the tagged Scottish smolts came from one river.

Lord Hughes referred to the difficulty and the importance of persuading Greenland fishermen that control was in their own interests and not just in the interests of people in other countries: international action was not within the control of Britain or even of Britain and Denmark. So far as the Danes were concerned, it had been confirmed that they were prepared to be helpful. For the joint tagging programme in Greenland waters, planned in co-operation with Danish scientists, and designed to show where the salmon in those waters went

if they were not caught there, Britain was receiving considerable help from the Danish authorities, who were contributing substantially to the cost of the equipment required and providing many of the facilities needed. They had also been co-operative in supplying the information about the Greenland fishery. For the same reason, at the recent meeting in Canada of the International Commission for the North-west Atlantic Fisheries, Britain joined with other nations in urging that all countries concerned should step up their investigation on salmon fisheries. After full discussion the Commission had drawn up a schedule of further information required for a proper assessment of the effect of the Greenland fishery on stocks

of the Atlantic salmon and commended it to all countries concerned. There had not yet been time to find out the full extent to which the Danish authorities could co-operate, and if remedial measures proved to be necessary they could only be taken by international action. There was a similar commission for the North-east Atlantic which relied for scientific advice on the International Council for the Exploration of the Sea, which was concerned, among other things, with salmon stocks native to European countries. Lord Hughes emphasized that Britain would keep in touch with developments, but he did not think that Britain could do more on the international side than she was doing at present.

## THE INSTITUTION OF GAS ENGINEERS

THE 102nd annual general meeting of the Institution of Gas Engineers was held at Solihull, near Birmingham, Warwickshire, during May 24-28, when several communications on diverse subjects of interest to members were read and discussed.

Among the papers presented\* was one by Dr. N. J. Sander and Dr. W. E. Humphrey (Exploration Department, American International Oil Company, New York) entitled "Why Look for Oil and Gas in the North Sea?" (now issued as Publication No. 677), one of the most informative, both geologically and technically, descriptions of the off-shore drilling areas in this basin yet to appear; the reasons for the venture are clearly stated, chances of success cautiously assessed, and inclusion of many maps and diagrams of simplified geological sections enables the reader to grasp without difficulty the fundamentals of North Sea geology and to assess for himself the ultimate possibilities of oil and gas recovery here.

J. W. Kerr (president, Canadian Gas Association) contributed a paper (678) on "Natural Gas in Canada", which described the phenomenal growth rate of the industry during the past seven years; while it is admitted that this rate cannot be repeated or maintained, the future growth prospects of the industry are viewed with justifiable

optimism. A paper (679) on "The Application of Work Study and Associated Techniques to Plant Maintenance" was presented by H. R. Hart (Scottish Gas Board), and confirms that, on the basis of results so far achieved, work study within the field of plant maintenance and having due regard to forward developments has more than proved its worth.

O. E. Mills discussed "Some Special Features of the Recent Developments in the East Midlands Gas Board" (680), which emphasized the enormous importance to the gas industry of the grid-main system in Great Britain, with special reference to the Killingholme Grid extension. A communication (682) by F. Bell, R. O. Emmony and P. E. Gallaher (West Midlands Gas Board), entitled "Keeping up the Pressure", concerns much that is administrative in the industry, especially since the advent of gas grids, the implication being "... pressure on staff, contractors, and suppliers of material and equipment". P. J. Savage (North Thames Gas Board) discussed (683) "The Production of Gas from Hydrocarbons, using the O.N.I.A. Continuous Autocaloric Process". "Part and Parcel" (684) is the title of a paper by W. V. Olsson and J. K. Mitchell (West Midlands Gas Board), which dealt with appliance spare-part service.

Finally, a paper on "Progress in Management Techniques" (685), by R. J. Maher (Australian Gas Light Company, Sydney), describes his company's "... effort to develop the conditions under which each sub-system and its objectives are compatible with and adaptive to the total Company objectives". The tremendous potentialities of the electronic computer for efficiently handling large and involved logical systems in management in the industry are particularly stressed.

## INDUCTION OF ADRENAL DAMAGE AND CANCER WITH METABOLITES OF 7,12-DIMETHYLBENZ(a)ANTHRACENE

By PROF. E. BOYLAND and DR. P. SIMS

Chester Beatty Research Institute, Institute of Cancer Research: Royal Cancer Hospital, Fulham Road, London, S.W.3

AND

PROF. C. HUGGINS

Ben May Laboratory for Cancer Research, University of Chicago

A CARCINOGENIC hydrocarbon, 7,12-dimethylbenz(a)anthracene (DMBA), differs from other members of this group of carcinogens in a number of ways that include:

(1) Being non-planar in the crystalline state, whereas most carcinogenic hydrocarbons are planar<sup>1</sup>. But the deviation from planarity of DMBA is not sufficiently great to prevent formation of donor-acceptor complexes with nitroaromatics.

(2) The ability to produce cancer in mice and rats in shorter periods of time than do other aromatic hydrocarbons.

(3) The ability to combine with DNA *in vivo* to a greater extent than do other hydrocarbons<sup>2</sup>.

(4) The property of "invariably, selectively and totally destroying two zones of adrenal cortex of the adult rat and the induction of adrenal apoplexy"<sup>3</sup>. Rats can be protected against this effect and from the lethal action of

large doses of DMBA by previous treatment with certain aromatic hydrocarbons and amines<sup>4</sup>. The protective compounds are those which cause increases in the activities of the microsomal enzymes that metabolize foreign compounds including many carcinogens.

(5) Whereas phenanthrene, benz(a)anthracene, dibenz(a,h)anthracene and other unsubstituted aromatic hydrocarbons are metabolized by oxidation of the double bonds to extents varying with the activity of these bonds in the molecules, DMBA is metabolized mainly by oxidation of the methyl groups to the hydroxymethyl derivatives, 7-hydroxymethyl-12-methylbenz(a)anthracene (7-OHM-12-MBA) and 12-hydroxymethyl-7-methylbenz(a)anthracene (12-OHM-7-MBA)<sup>5</sup>. The amounts of the hydroxymethyl derivatives accumulating in rat-liver microsomes are reduced if the animals from which the microsomes are prepared are first treated with substances that induce increases in microsomal enzymes and that reduce the adrenal damage in rats caused by DMBA.

Because DMBA appeared to be unique in its action on the adrenal glands and in its metabolism and because these characteristics were changed by compounds that induce microsomal enzymes, it appeared probable that one or other of the metabolites of DMBA might be responsible for the specific effect on the adrenal.

Groups of female rats of the Sprague-Dawley strain at about 50 days of age were given single doses of DMBA, 7-OHM-12-MBA or 12-OHM-7-MBA, dissolved in sesame oil, by gastric instillation. The rats were killed three days later and the adrenals weighed and examined. The results (Table 1) show that DMBA, and one of its metabolites, 7-OHM-12-MBA, cause adrenal damage as indicated by histological change (apoplexy), increase in weight of the gland and increase in the haemoglobin content of the gland. 7-OHM-12-MBA was more active than the hydrocarbon, as 5 mg of 7-OHM-12-MBA caused about the same amount of damage as 30 mg of DMBA. The isomeric 12-OHM-7-MBA was inactive even in 60-mg doses. The potency of DMBA to induce adrenocorticalysis is thus enhanced by hydroxylation at position 7, whereas it is eliminated by introduction of OH group on the methyl group at position 12.

7-Hydroxymethylbenz(a)anthracene (7-OHMB) did not destroy adrenals, indicating that the methyl group in the 12-position is essential for this biological activity. DMBA increases the activity of the enzyme menadione reductase in the livers of rats<sup>6</sup>; 7-OHM-12-MBA (Table 2) also increases this enzyme, but not so effectively as DMBA.

The carcinogenic activities of the metabolites of DMBA have been tested by gastric instillation into female

Table 1. EFFECT ON ADRENAL OF DIMETHYL- AND HYDROXYMETHYL-DERIVATIVES OF BENZ(a)ANTHRAcene

Benz(a)anthracene derivative	No. of rats	Dose (mg)	Adrenal		
			Weight (mg)	Apoplexy	Haemoglobin* (g)
None: controls	10	—	22 ± 2	0/20	63 ± 15
7,12-Dimethyl	10	30	43 ± 8	20/20	499 ± 101
7-Hydroxymethyl	1	60	21	0/2	45
7-Hydroxymethyl-12-methyl	3	2	24 ± 1	0/6	53
Same	3	5	23 ± 6	6/6	655
12-Hydroxymethyl-7-methyl	6	30	21 ± 3	0/12	76

Sprague-Dawley female rats, age 47 days, weight 147–150 g, were given by gastric instillation a single dose of the aromatic dissolved in sesame oil. The adrenals were collected at age 50 days.

\* Standard deviation.

\* When 1 adrenal of a rat contains less than 125 µg of oxyhaemoglobin it is considered to be free from haemorrhage. Values greater than this are diagnostic of adrenal apoplexy.

TABLE 2. INDUCTION OF MENADIONE REDUCTASE IN LIVER

Benz(a)anthracene derivative	Dose (mg)	No. rats	Menadione reductase (units/g)	(%)
Control: no compound	—	15	20 ± 2	100
7-Hydroxymethyl	30	10	22.7	113
7-Hydroxymethyl-12-methyl	10	3	28.4	142
7-Hydroxymethyl-12-methyl	30	3	34.4	172
7,12-Dimethyl	10	3	50.7	253

Rats were given by gastric instillation a single dose of aromatic dissolved in sesame oil at age 47 days; a sample of liver was obtained under ether anaesthesia 24 h later. One unit of menadione reductase is defined as the enzyme activity which reduces 1 µmole of DPNH/1 min under stated conditions.

Table 3. INDUCTION OF CANCER BY FEEDING DMBA AND DERIVATIVES TO RATS

Benz(a)anthracene derivative	Dose (mg)	No. of rats	Cancer yield	Appearance of palpable mammary cancer (days) Range	Mean
7-Hydroxymethyl-12-methyl	10	10	7/10	49–119	87
12-Hydroxymethyl-7-methyl	20	5	0	—	—
7,12-Dimethyl	10	19	15/19	28–76	43

Female Sprague-Dawley rats were fed a single meal of the aromatic dissolved in 1 ml. of sesame oil at age 50 days.

Table 4. INDUCTION OF SARCOMA IN RATS

Benz(a)anthracene derivatives	No. of rats	No. of rats with sarcoma 8 months after injection	Time of detection in days
7,12-Dimethyl	8	8/8	97–137 (110 ± 14)
7-Hydroxymethyl-12-methyl	8	2/8	153
12-Hydroxymethyl-7-methyl	8	0	—

Compounds (2.5 mg in 0.5 ml.) sesame oil were injected into the thigh muscle of 46-day-old Sprague-Dawley rats which were observed for 8 months.

Table 5. INDUCTION OF TUMOURS IN C57 MICE

Benz(a)anthracene derivatives	No. of mice	Sex	No. of mice with tumours	Time of appearance of tumours in days
7-Hydroxymethyl-12-methyl	20	Male	16	119
7-Hydroxymethyl-12-methyl	20	Female	14	127
12-Hydroxymethyl-7-methyl	10	Male	9	119
12-Hydroxymethyl-7-methyl	10	Female	4	119

Mice were injected with 1 mg of the compound in 0.5 ml. arachis oil weekly for 10 weeks.

Sprague-Dawley rats and by subcutaneous injection into rats and mice. DMBA and some other carcinogens induce mammary cancer in a few weeks in female Sprague-Dawley rats<sup>6</sup>. 7-OHM-12-MBA had about the same (but not greater) activity in inducing these tumours as DMBA, but the mean induction time was twice as long (Table 3). The other metabolite, 12-OHM-7-MBA, did not induce these tumours, although it was given in larger doses. This indicates that the oxidation of DMBA to 12-OHM-7-MBA is a detoxicating process. The mammary tumour-inducing activity of DMBA might be exerted after conversion into 7-OHM-12-MBA, but this is not certain.

The results of single injection experiments in rats (Table 4) in eliciting sarcoma show that DMBA is more active than are the metabolites. Tests in mice (Table 5), in which ten weekly injections were given, show that both the metabolites were carcinogenic under these conditions. DMBA injected as single 1-mg doses into mice caused a number of deaths, showing that the hydrocarbon is more toxic than the related hydroxymethyl compounds. It is of interest that 12-OHM-7-MBA appears to be an active carcinogen in mice, but did not elicit tumours in rats.

Both DMBA and 7-OHM-12-MBA are strong electron donors and gave red colours with a chloroform solution of 1,3,5-trinitrobenzene, whereas 12-OHM-7-MBA is a weak donor. It is not clear at the moment whether or not these properties are related to the biological activities of the compounds.

This investigation was supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the Medical Research Council and the British Empire Cancer Campaign for Research, and by the Public Health Service grant CA-03188-08 from the National Cancer Institute, U.S. Public Health Service, and by grants to the Ben May Laboratory for Cancer Research from the American Cancer Society and the Jane Coffin Childs Memorial Fund for Medical Research.

# PHYTOHAEMAGGLUTININ-INDUCED CYTOTOXIC ACTION OF UNSENSITIZED IMMUNOLOGICALLY COMPETENT CELLS ON ALLOGENEIC AND XENOGENEIC TISSUE CULTURE CELLS

By DR. GÖRAN HOLM\* and PROF. PETER PERLMANN\*

Wenner-Gren Institute for Experimental Biology, University of Stockholm, and Department of Medicine, Serafimer Hospital, Stockholm

IN a previous article we reported that lymphoid cells from spleen, lymph nodes, thoracic duct lymph or blood of non-immune humans or rats were cytotoxic for tissue culture cells of human or rat origin, when incubated together with such cells in the presence of phytohaemagglutinin (PHA)<sup>1</sup>. The medium from PHA-treated lymphocytes was not cytotoxic and separation of lymphocytes from tissue culture cells by means of a 'Millipore' membrane also prevented such an effect. Similar results have recently been reported by others<sup>2,3</sup>.

The target cell killing observed in these experiments may have been the expression of an immune response of the lymphocytes, induced by their close contact with the target cells and possibly potentiated by PHA. However, it was also feasible that cell damage was brought about in an entirely non-specific way. In all experiments performed at that time, lymphoid cells and target cells differed in regard to their histocompatibility antigens. It was anticipated that no effects would appear in syngeneic lymphocyte/target cells combinations, if the target cell killing indeed had an immunological basis<sup>1</sup>. Furthermore, if this was the case, it could be assumed that the cytotoxic activity of the lymphocytes should be related to their immunological competence. The experiments described in this article aimed at an elucidation of these important points.

Primary cultures and first sub-cultures were set up from kidneys of new-born rats or from embryonic rat or mouse fibroblasts. The rat cells were from rats of the highly inbred *R*-strain, reared by brother-sister mating for more than 40 generations and with no transplantation incompatibilities between different individuals. The mouse fibroblasts originated from inbred *A/Sn* mice (*H-2<sup>k</sup>/H-2<sup>k</sup>*). The culture conditions, isotope labelling (2  $\mu$ C-<sup>14</sup>C-thymidine (spec. act. ~30 mc./mmole) in 15 ml. of culture medium) and further handling of the material have been described<sup>1</sup>. In some experiments, kidney cells from outbred, new-born Sprague-Dawley rats were also used. These cells had been grown in suspension culture for 6 months. For isotope labelling,  $3 \times 10^7$  cells were grown for 2-3 days in 40 ml. of medium containing 2  $\mu$ C-<sup>14</sup>C-thymidine. After three washings, the cells could then be used for incubation with lymphocytes without further processing.

Lymphoid cells from rat (female) or mouse spleen, lymph nodes or thymus (*R*-strain or Sprague-Dawley rats, *A/Sn*, *UBA* (*H-2<sup>k</sup>/H-2<sup>k</sup>*) or outbred mice) were prepared by suspending the tissue in balanced salt solution, cutting it into small pieces and finally dispersing the cells by repeated pipetting. Clumps and debris were removed by sedimentation. Lymphocytes from human or rat peripheral blood were isolated by the gelatine method of Coulson and Chalmers<sup>4</sup>. <sup>14</sup>C-isotope-labelled and washed target cells were incubated in roller tubes under sterile conditions with an excess of lymphoid cells as previously described<sup>1</sup>. The procedure is outlined in Fig. 1. Samples containing more than 10 per cent dead cells at the beginning of incubation were discarded. Parker's Medium 199 contain-

ing 5 per cent foetal calf serum was used throughout. <sup>14</sup>C-thymidine (final concentration 10  $\mu$ g/ml.) was added in order to prevent isotope re-utilization. The lymphoid cells were added 2 h later immediately followed by PHA. The final concentration of PHA (Difco, phytohaemagglutinin M) was 0.3 mg/tube. The final volume of the incubation mixtures was 1.5 ml. The further handling of the samples followed the description given earlier<sup>1</sup>. As found earlier, the bulk of DNA-bound radioactivity from dead or damaged cells was first released after trypsin treatment of sediment (Fig. 1) and this release could then be used as a measure of cell damage<sup>5,1</sup>. A critical evaluation of this method will be found elsewhere<sup>6</sup>.

Fig. 1. Procedure for determining the cytotoxic action of lymphocytes on tissue culture cells

Table 1 shows the typical results of series of experiments in which *R*-strain fibroblasts were incubated with spleen cells from syngeneic *R*-strain rats or from mice of an outbred laboratory colony. Fig. 2 shows a summary of this and two similar sets of experiments, in which the target cells were either from inbred rats or inbred mice. The dashed line represents isotope release, and the shaded area its 95 per cent confidence limits, in those controls which contained lymphocytes but not PHA. The results of these and similar experiments may be summarized as follows: (1) Damage of the target cells in the presence of syngeneic lymphoid cells was the same, regardless of whether or not PHA was added to the tubes. It was

\* Present address: Wenner-Grens Institut, Norrtullagatan 16, Stockholm Vs, Sweden.

Fig. 2. Cytotoxic action of lymphoid cells of different genetic origin on various tissue culture cells. The three columns represent three sets of experiments performed with the target cells (primary cultures) indicated on top of each column. The ordinates give the percentage of isotope released from the target cells (Fig. 1). Each symbol represents a separate lymphocyte/target cell incubation. Squares, xenogeneic lymphoid cells (first column: spleen cells from Sprague-Dawley rats; third column: lymph node cells from outbred mice); black circles, allogeneic lymphoid cells (first column: spleen cells from OBA-mice; second column: lymph node cells from Sprague-Dawley rats); white circles, lymphoid cells (first and second column: lymph node cells; third column: spleen cells) syngeneic with the target cells indicated in the figure. Triangles, no lymphoid cells added.

sometimes, but not always, moderately elevated over that found in the absence of lymphocytes, probably due to cell crowding or other non-specific causes. (2) *Allogeneic* lymphocytes had the same effect as syngeneic lymphocytes when PHA was absent. However, in the presence of PHA, the target cell damage was significantly elevated. (3) *Xenogeneic* lymphocytes always gave a pronounced target cell damage in the presence of PHA. A slight, but significant, effect as compared with the controls sometimes also appeared without PHA. Finally, it should be stressed that the PHA-induced lymphocyte/target cell aggregation was always the same when observed in the microscope, regardless of the genetic relationships between the cell types.

Table 1 Target cells: Rat, R-strain fibroblasts (prim.). Lymphocyte/target cell ratio: 100:1. Incubation: 48 h			
Lymphoid cells	PHA	C.p.m. in DNA (Sup. II + Sed. II)	% Isotope release
Mice spleen	-	1,228 ± 92	18.9 ± 4.4
Mice spleen	+	1,121 ± 24	28.5 ± 2.4
Rat spleen (R-strain)	-	1,178 ± 220	10.7 ± 2.1
Rat spleen (R-strain)	+	1,217 ± 40	14.2 ± 2.9
-	-	1,223 ± 77	6.9 ± 1.1
-	+	1,220 ± 28	9.7 ± 0.9

The numbers represent mean values and S.D., each based on three different experiments.

These results strongly suggested that the cell-killing effect of the lymphocytes had indeed an immunological basis. Similar results have recently been reported by E. Møller<sup>2</sup>, using normal lymph node cells and tumour cells from mice in different H-2 combinations. This author

also made the very interesting observation that lymph node cells of semi-isologous F<sub>1</sub> hybrid origin killed tumour cells of parental strain origin. Since the F<sub>1</sub> lymphoid cells were considered to be 'genetically incompetent' of reacting immunologically against parental strain H-2 antigens, the cell-killing phenomenon was interpreted as reflecting a mutual contact inhibition of cells differing in surface structure.

In order to examine the mechanism of this reaction, we have performed several different types of experiments. In a first series, isotope-labelled rat tissue culture cells were mixed with excessive numbers of unlabelled tissue culture cells of syngeneic, allogeneic or xenogeneic origin. These mixtures were then incubated for 48 h in the presence or absence of PHA. When present, PHA was seen to cause the formation of mixed aggregates. In some cases, isotope release was high (35-40 per cent), regardless of the cell combination used, but increase of isotope release due to PHA was never seen. Similarly, no cell damage was obtained when a very large excess of mouse red blood cells and PHA were added to labelled rat tissue cells.

In a second series of experiments, it was attempted to establish close lymphocyte/target cell contacts without using PHA. Rosenau has previously shown that addition of polylysine and allogeneic lymphocytes to mouse fibroblasts in monolayers resulted in firm aggregations but no cell damage<sup>7</sup>. Similar experiments performed by us also yielded negative results (Table 2), in spite of strong lymphocyte/target cell aggregations. The relatively pronounced cell damage in the lymphocyte-free polylysine controls indicated that this substance was toxic by itself at the concentrations used. Rosenau and Moon have also shown that incorporation of hydrocortisone in the medium abolished the cytotoxic effects of immune lymphocytes without preventing their aggregation to the target cells<sup>8</sup>. The same was seen in our experiments with normal lymphocytes and PHA. Similarly, addition to the target cells of lymphocytes, killed either by heating (56°C, 30 min) or by freezing and thawing (4 times), also abolished their cytotoxic effects. A typical experiment is shown in Table 3.

Table 2					
Target cells: rat kidney (cell line). Lymphocytes: human (periph. blood).					
Lymphocyte/target cell ratio: 60:1. Incubation: 48 h					
	Exp. 1		Exp. 2		
Incubation	C.p.m. in DNA (Sup. II + Sed. II)	% Isotope release	C.p.m. in DNA (Sup. II + Sed. II)	% Isotope release	
Lymphocytes -	403 ± 20	17.5 ± 3.4	1,210 ± 198	11.7 ± 2.1	
Lymphocytes + PHA	452 ± 35	27.9 ± 3.4	1,116 ± 80	28.3 ± 7.8	
Lymphocytes + polylysine	390 ± 132	19.2 ± 1.6	1,025 ± 25	14.8 ± 1.0	
— + PHA	499 ± 35	5.7 ± 0.4	1,058 ± 49	19.9 ± 1.7	
— + polylysine	459 ± 34	23.0 ± 0.1	1,112 ± 120	25.1 ± 1.0	
— —	458 ± 12	17.7 ± 8.0	1,065 ± 11	21.5 ± 2.6	

Exp. 1: 1 µg polylysine/ml. Exp. 2: 5 µg polylysine/ml. The numbers represent mean values and S.D., each based on three separate experiments.

Table 3 Target cells: rat kidney (cell line). Lymphocytes: human (periph. blood). Lymphocyte/target cell ratio: 40:1. Incubation: 48 h			
Lymphocytes	PHA	C.p.m. in DNA (Sup. II + Sed. II)	% Isotope release
+	-	1,001 ± 100	8.7 ± 1.7
+	+	886 ± 84	25.9 ± 5.7
+	(killed)	887 ± 104	6.2 ± 1.3
+	(killed)	961 ± 153	4.0 ± 1.0
-	-	1,125 ± 103	8.8 ± 1.0
-	+	1,006 ± 89	7.9 ± 1.0

The figures represent mean values and S.D., each based on three separate experiments.

When taken together, these results suggested (but did not prove) that living lymphoid cells had to be added to the incubation mixtures if cytotoxic effects were to occur. In order to investigate the possible relationship of this cell-killing activity of lymphoid cells to their immunological competence, the action of peripheral lymphocytes was compared with that of lymphocytes from the thymus.

Such cells were isolated from young mice (randomly bred), and material from the same individual animals was used in each experiment. When added to tissue culture cells in monolayers in the presence of PHA, thymus lymphocytes were seen aggregated around the former to the same extent as peripheral lymphocytes (Fig. 3). However, as seen from the typical results of Fig. 4, thymocytes gave no or only weak cytotoxic effects in cases where peripheral lymphocytes were active. This difference was not due to a lesser viability of the thymocytes. When samples of these cells were kept separately for 48 h under otherwise similar conditions, the survival rates of both peripheral lymphoid cells and thymocytes was approximately 40 per cent in all cases.

The lesser reactivity of the thymocytes found in our experiments corresponds to that seen by others in different immunological situations (for references and discussion see ref. 9). It may be concluded that the cell-damaging activity of lymphocytes as measured here is related to their 'immunological competence'. Therefore, we believe that the target cell damage reflects a response of competent lymphocytes, started by their close contact with antigen which they recognize as 'foreign', and perhaps potentiated by PHA<sup>10</sup>. The action of lymphoid cells of  $F_1$  hybrid origin on parental strain tumour cells can probably also be explained on this basis. The notion of a 'genetic incompatibility', such that the  $F_1$  lymphoid cells do not react against parental cells<sup>6</sup>, is based on the fact that no such reactions occur in normal transplantation or graft-versus-host situations. It may be recalled that slight structural changes of a variety of antigens may sometimes give rise to a loss of natural tolerance and ensuing autoimmune responses<sup>11</sup>. In analogy, and as example only, small differences in cell surface structure of parental and  $F_1$  cells due to different arrangement or concentration of histocompatibility antigens may be sufficient to release a response of competent lymphocytes when the cells are tightly aggregated in this highly artificial manner.

The statement that the present reactions reflect an immune response of competent lymphoid cells requires qualification. While there is little doubt that the response is initiated by an immunologically specific recognition step, no evidence exists as yet for a corresponding specificity of the target cell destructing reactions. In other words, the response does not necessarily have to involve antibody formation. Although available evidence

Fig. 3. Rat fibroblasts on cover slip, incubated with mice thymocytes for 12 h in the presence of PHA. Micrograph (phase contrast) of living cells ( $\times 400$ ).

Fig. 4. Cytotoxic action of thymocytes and peripheral lymphoid cells on various tissue culture cells. The target cells were R-strain rat fibroblasts in the experiments of the first column and rat kidney cells (Sprague-Dawley, established cell line) in the experiments of the second column. Black circles, peripheral lymphoid cells from lymph nodes (first column) and spleen (second column) of randomly bred mice. White circles thymocytes from the same animals used as donors of peripheral lymphocytes. For further explanations see legend to Fig. 2.

speaks against the release of pharmacologically active agents from the stimulated lymphocytes to the incubation medium, a local action of such agents in the contact areas between the cells cannot be excluded<sup>1</sup>. A third alternative would be that the aggregated lymphocytes are metabolically stimulated by foreign antigen and therefore damage the target cells by depriving them of nutrients or oxygen. However, this explanation seems difficult to reconcile with the negative results seen in syngeneic lymphocyte/target cell aggregations in which PHA should have affected the metabolism of the lymphocytes in a similar way to antigen.

In our experiments, the lymphocyte response was most probably induced by their contact with foreign histocompatibility antigens. Obviously, as seen in syngeneic systems, the presence of organ-specific substances on the target cells was not sufficient to release a significant response. This raises the interesting problem as to the mechanism of target cell destruction, observed in similar experiments with lymphoid cells from 'autoimmune' animals<sup>12,6</sup> or human beings<sup>13</sup>. In those experiments, lymphocyte/target cell contacts were most probably established by antibody or antibody-like substances on the lymphocytes. However, in all cases described so far, lymphocytes and target cells were derived from genetically different individuals. Therefore, the target cell-damaging activities of the lymphocytes may also have been released by their close contact with foreign histocompatibility antigens. Experiments with lymphocytes from autoimmune animals, added to target cells of syngeneic origin, should throw light on this point. Such experiments are in progress.

Many other questions remain. In particular, one would like to know the relationship of the phenomenon described here to the lymphocyte transfer reaction<sup>14</sup>, or to the *in vitro* stimulation of lymphocytes, occurring on exposure to foreign cells<sup>15</sup> or antigen<sup>16</sup>. The type of the lymphoid cells which participate in the reaction is unknown at present and one also wonders whether the reactors are immunologically committed or uncommitted cells. The true function of PHA in the present system will also have to be investigated further. Nevertheless, experiments of the kind described in this article would seem to offer some means for investigating the mechanism by which lymphoid cells recognize 'foreignness', and the relation-

ship of the recognition step to the response evoked by it in the competent lymphocytes.

## INHIBITION BY METHOTREXATE OF TRIIODOTHYRONINE STIMULATION OF OXYGEN CONSUMPTION IN MAN

By DR RICHARD S. RIVLIN and PROF. ALBERT H. OWENS, jun.

THYROXINE has been shown to stimulate the rate of incorporation of amino-acids into protein<sup>1-3</sup>. It has recently been suggested that the well-recognized effects of thyroid hormones on oxygen consumption may be related to their effects on protein biosynthesis<sup>4-6</sup>. Thyroxine administration to rats results in increased rates of amino-acid incorporation into protein only in organs (liver, kidney and heart) in which the hormone also stimulates oxygen consumption, but has no effect on amino-acid incorporation into protein in organs (brain, testis and spleen) in which oxygen consumption is unaffected<sup>4</sup>. Drugs such as puromycin and actinomycin D, which result in an inhibition of protein biosynthesis, also block the effects of thyroid hormones on oxygen consumption<sup>5,6</sup>. These experiments provide further evidence of a relationship between the effects of thyroid hormones on protein biosynthesis and on oxygen consumption.

The present investigation was undertaken to determine whether methotrexate (amethopterin) treatment of human subjects counteracts the effects of thyroid hormones in a manner similar to that shown for puromycin in experimental animals. Investigations were carried out on two male patients, aged sixty-two and fifty-four years, with advanced metastatic carcinoma of the lung. Two patients were hospitalized in a metabolic ward, and received constant caloric and protein intake during the investigation. Each patient was euthyroid at the beginning of the investigation, as demonstrated by clinical examination and by normal values of serum protein-bound iodine concentration, serum cholesterol concentration, and basal metabolic rate. The measurements of basal metabolic rate were made by standard methods, with standard corrections applied for changes in body temperature and weight during the course of the investigation.

After baseline evaluation of thyroid function of the first patient had been completed (protein-bound iodine = 6.4 µg/100 ml. serum; serum cholesterol concentration = 175 mg/100 ml. serum; basal metabolic rate = +6 per cent), triiodothyronine was given orally in doses of 75 µg four times a day for a period of nine days. During this interval there appeared a loss of weight of 8.5 kg, a decrease in serum cholesterol concentration from 175 to 115 mg per cent, and increased sweating, nervousness and tachycardia. Basal metabolic rate (Fig. 1) increased progressively from baseline levels of +6 and +10 to a level of +65 per cent after treatment with triiodothy-

ronine. From the tenth to the sixteen day, methotrexate was administered intravenously at a dosage of 0.2 mg/kg body-weight a day. Daily determinations of haemoglobin concentration, haematocrit, white cell count and differential count were performed to evaluate drug toxicity. Triiodothyronine treatment was continued until the eighteenth day. Basal metabolic rate declined from a level of +65 before methotrexate treatment to levels of +19 and +26 per cent following the completion of seven days of methotrexate therapy, despite the continuance of triiodothyronine.

To evaluate further the effects of methotrexate in the patient under investigation, the antibody response to two different antigens was measured. Four h after the first dose of methotrexate had been given on day 10, the patient received 0.4 ml. of V<sub>8</sub> antigen (*E. coli*) by subcutaneous injection. Serial samples of serum were obtained before injection of antigen on day 10, and on days 14, 17, 20 and 24. During the two-week period following injection of antigen, no antibody titre could be detected, in contrast to mean titres (log<sub>10</sub> serum dilution) found in patients previously studied<sup>7</sup>. On day 24, the patient received 1.0 ml. of whole, killed tularemia vaccine by subcutaneous injection. Serum samples obtained during the ensuing two weeks had normal antibody titres.

Fig. 1. Measurements of basal metabolic rate in the first patient studied, during administration of triiodothyronine, and of triiodothyronine in combination with methotrexate. Results are expressed as a percentage

In the second patient, baseline evaluation of thyroid function revealed that the serum protein-bound iodine concentration was  $6.9 \mu\text{g}/100 \text{ ml. serum}$ , cholesterol concentration was  $220 \text{ mg}/100 \text{ ml. serum}$  and basal metabolic rate was  $+9 \text{ per cent}$ . Constant caloric and protein intake were maintained in a manner similar to the first study. The measurements of basal metabolic rate are shown in Fig. 2. Methotrexate in the same dosage ( $0.2 \text{ mg/kg}$ ) was given by daily intravenous injection for a period of five days. Basal metabolic rate measurements before methotrexate did not differ significantly from values observed in the week after treatment. After an additional period of ten days had elapsed, which enabled the patient to recover from mild drug toxicity, triiodothyronine treatment was begun. At the end of nine days of treatment (day 24), loss of weight of  $4.6 \text{ kg}$  was noted, in association with tachycardia, nervousness, sweating, irritability and depression of the serum cholesterol concentration from  $220$  to  $135 \text{ mg}/100 \text{ ml. serum}$ . Basal metabolic rate levels had increased from control values of  $+5$  and  $+8$  to a level of  $+55 \text{ per cent}$ . Methotrexate was again administered for five days while triiodothyronine was continued. Following the completion of methotrexate administration, the basal metabolic rate had declined to  $+38 \text{ per cent}$ , and two days after discontinuing triiodothyronine treatment, the basal metabolic rate had declined still further to a level of  $+13 \text{ per cent}$ .

The work recorded here indicates that in the two patients investigated, the effect of triiodothyronine on elevating the basal metabolic rate was antagonized by treatment with methotrexate. In addition, during the period of methotrexate treatment, and for seven days following cessation of treatment, there was complete prevention of antibody synthesis after injection of Vi antigen. This effect may represent impairment of protein synthesis, although other factors are also involved in response to an antigenic stimulus. That prevention of antibody synthesis was only temporary was shown by our subsequent finding of a normal antibody response to tularaemia vaccine in the same patient.

By blocking the enzymatic reduction of folic and dihydrofolic acids<sup>1-3</sup>, methotrexate interferes with one-carbon transfer in many important biochemical reactions. Of particular importance is this effect on the synthesis of pyrimidines and purines. Following diminished formation of nucleotides, reduced synthesis of proteins would be expected to occur.

In the work recorded here, methotrexate treatment partially antagonized the stimulatory effects of triiodo-

Fig. 2. Measurements of basal metabolic rate in the second patient studied, during administration of methotrexate and triiodothyronine separately, and of both drugs together. Results are expressed as a percentage.

thyronine on oxygen consumption. No effect on oxygen consumption was demonstrable in the absence of excess thyroid hormone. Since the actions of methotrexate on metabolism are numerous, it is not possible to attribute these results with certainty to a particular effect of the drug. However, the similarity of the present results to those previously obtained with agents which more specifically inhibit protein synthesis (actinomycin, puromycin) suggest that the pertinent effect of methotrexate may also have been on protein synthesis.

## NEW MODEL FOR THE TROPICOLLAGEN MACROMOLECULE AND ITS MODE OF AGGREGATION

By DR. R. A. GRANT, DR. R. W. HORNE and DR. R. W. COX

Agricultural Research Council, Institute of Animal Physiology, Babraham, Cambridge

THE molecular architecture of collagen has been intensively studied by a variety of physical and chemical techniques. According to current views collagen fibres are composed of fibrils which are themselves built up from a basic structural unit termed the tropocollagen macromolecule. Each tropocollagen unit is believed to have a three-stranded coiled-coil structure in which the most probable arrangement of the polypeptide chains would appear to be the collagen II model proposed by Rich and Crick<sup>1</sup>. The tropocollagen unit has been described as a rigid rod-like structure for which Boedtker and Doty<sup>2</sup>, using physico-chemical methods, originally found a diameter of  $13.6 \text{ \AA}$ , an average length of  $3000 \text{ \AA}$

and an average molecular weight of  $345,000$ . Recently, Rice, Casassa, Kerwin and Maser<sup>3</sup> have suggested a length of  $2800 \text{ \AA}$  and a molecular weight not greater than  $310,000$ .

One of the earliest observations made on biological material with the electron microscope was that native collagen fibres exhibited a conspicuous transverse banding with a repeat distance of approximately  $640 \text{ \AA}$  (Schmitt, Hall and Jakus<sup>4</sup>; Wolpers<sup>5</sup>). There have since been many reports on the structure of collagen using shadowing, thin sections and positive staining. These have been reviewed in detail by Harrington and Von Hippel<sup>6</sup>, Gross<sup>7</sup>, Fittin Jackson<sup>8</sup> and Veis<sup>9</sup>. Much research has been

devoted to clarifying the relationship of the basic tropocollagen unit to the native collagen fibre.

An important aspect of the problem is to explain how the observed periodicity of 640 Å of native collagen results from the combination of tropocollagen units of length 2800 Å.

It is well known that native-type collagen fibres may be reconstituted from acetic acid solutions of collagen by adjustment of pH and ionic strength. It is also possible to reconstitute collagen in a number of forms differing characteristically from the native fibre. A particularly interesting form is the segment long spacing (SLS) crystallites (Gross, Highberger and Schmitt<sup>10</sup>) produced by the addition of adenosine triphosphate (ATP) to an acetic acid solution of collagen. The SLS crystallites appear to consist of tropocollagen units aggregated side by side with the ends of the molecules in register. A large number of bands, arranged at right angles to the long axes of the tropocollagen units, may be seen with the electron microscope using either positive- or negative-staining techniques. The fact that these bands are distributed asymmetrically is strong evidence that the structure of the tropocollagen macromolecule is polarized.

Another type of collagen fibril, produced by dialysing an acetic acid solution of collagen (tropocollagen) containing acid glycoprotein or chondroitin sulphate (Highberger, Gross and Schmitt<sup>11</sup>; Schmitt, Gross and Highberger<sup>12</sup>) has been termed the fibrous long spacing (FLS) form. The repeat distance of this form has been found to vary with the method of preparation and the different varieties produced have been further designated FLS—I, II, etc., depending on the spacing observed. In the case of the FLS form of collagen a maximum repeat distance of about 2500 Å has been found. It has been suggested (Schmitt and Hodge<sup>13</sup>) that in the FLS form of fibre the tropocollagen units are aggregated end to end. The direction of polarization of the macromolecules was considered to be alternated in view of the symmetrical pattern obtained in the electron microscope after positive staining with phosphotungstic acid.

Application of the negative staining technique (Brenner and Horne<sup>14</sup>) to high-resolution studies of collagen with the electron microscope showed that it was possible to visualize, directly, tropocollagen macromolecules occurring in native collagen fibrils (Tromans *et al.*<sup>15</sup>; Olsen<sup>16,17</sup>). In their negatively stained preparations of collagen fibrils the most striking feature seen was the arrangement of slender, somewhat crooked filaments running roughly parallel to each other along the long axis of the fibril. These filaments, 15–20 Å across, were interpreted as being the tropocollagen macromolecules.

In a detailed study of negatively stained collagen specimens, Tromans<sup>15</sup> suggested that the light and dark bands resulted from differences in the density of the protein and in the penetration of the negative stain between the macromolecules. It was not found possible to demonstrate the precise positions of the ends of the macromolecules within the fibrils, nor was there any evidence in favour of a 'quarter staggered' arrangement as suggested by the model of Hodge and Schmitt<sup>18</sup>. The recent descriptions of native and FLS-type collagen by Olsen<sup>16,17</sup> and Kuhn and Zimmer<sup>19</sup> have indicated that the macromolecules are aggregated by end overlap. This view is not in agreement with the model proposed by Schmitt and Hodge<sup>18</sup>, in which it is suggested that end-to-end aggregation takes place by a coiling around each other of polypeptide chains projecting from each end of the tropocollagen macromolecule (Hodge and Petruska<sup>21</sup>).

This report is based on an electron microscope investigation on native, SLS and FLS forms of collagen, and on these same forms modified by treatment with various cross-linking agents. Our experiments have also included observations on the mode of aggregation of tropocollagen to the above forms. The effect of collagenase on native fibres was also investigated, in experiments which will be

reported in greater detail elsewhere. Acetic acid solutions of rat-tail tendon and guinea-pig skin collagen were used as sources of tropocollagen. From these investigations, a model has been developed which explains, in a relatively simple manner, the production of the majority of collagen forms. Their characteristic spacings can be considered to be determined by a basically random process of aggregation of tropocollagen units.

It was considered important to elucidate the mechanism whereby the light and dark bands, seen in negatively stained preparations of collagen, are produced. Treatment with a cross-linking agent, such as glutaraldehyde, resulted in an increase in the size of the light bands (A bands, Fig. 1, *b* and *c*; a well-defined light band also appeared in the dark or B bands. It was obvious from marked changes in the chemical and physical properties of the treated fibres (for example, no longer being soluble when autoclaved with water) that a number of strong cross-links had been introduced. Since the introduction of intermolecular cross-links by mild chemical means resulted in an increase in the size of the light or electron-transparent bands we may infer that the light bands, seen in native unaltered collagen, also result from regions of bonding between adjacent macromolecules. In native collagen this intermolecular bonding probably consists of polar and hydrogen bonds arising from polar amino-acid side-chains arranged in a structurally complementary manner. It thus appears that the tropocollagen units, forming the fibril, are not laterally bonded uniformly throughout their length. Such a concept is in conformity with the finding that the primary structure of collagen consists of inhomogeneous amino-acid sequences (Grassman *et al.*<sup>22</sup>).

Fig. 1. *a*, Electron micrograph of negatively stained SLS crystallite. The length of the crystallite spans five A bands of the native fibril, shown in *b* at the same magnification. *b*, Negatively stained collagen fibril showing regions of light A bands and dark B bands. The rather flexible tropocollagen macromolecules are seen arranged roughly parallel to the fibril long axis. *c*, Negatively stained collagen fibril following treatment with glutaraldehyde. The increase in both size and density of the A bands is demonstrated. A well-defined light band within the B zone is also apparent.

In order to deduce a simple rational explanation of the relationship of the length of the tropocollagen macromolecule (c. 2800 Å) to the normal repeat distance ( $D$ ) of 640 Å, use may be made of the observation that the length of an SLS crystallite spans 5  $A$  bands of a native fibril when electron micrographs at the same magnification are compared (see Fig. 1, *a* and *b*). On average, the length of an  $A$  band (light) is about  $0.4D$ ; hence the length of the tropocollagen unit equals the total distance spanned by 5  $A$  bands plus the intervening  $B$  bands ( $=4.4D$ ). Careful examination of the electron micrographs gives no evidence of end-to-end junctions, all the macromolecules appearing to be aggregated together by lateral association with a good deal of cross-over in both  $A$  and  $B$  bands. The precise positions of the ends of tropocollagen macromolecules within the fibrils were difficult to determine. However, on careful inspection of the electron micrographs instances were noted of tropocollagen filaments appearing to end at the edge of an  $A$  band after passing through the band.

We suggest, on the basis of this evidence, that the tropocollagen macromolecule consists of alternating bonding and non-bonding regions, the bonding regions containing polar amino-acids which are arranged in a structurally specific manner. When two such bonding regions approach one another closely in proper alignment a strong lateral attraction results from the formation of many intermolecular polar and hydrogen bonds. All the 5 bonding regions may not be exactly equivalent and there is some evidence that the terminal bonding zones differ from the intermediate ones. Examination of the SLS form, by positive or negative staining, indicates that the tropocollagen macromolecule is polarized, and this is supported by the fact that in native fibres the band structure is asymmetrical. Tromans *et al.*<sup>12</sup> have suggested that the light bands be regarded as regions of crystallographic disorder. In view of the evidence from the cross-linking experiments we feel that this interpretation may be abandoned in favour of the more definitive explanation that the light bands correspond to regions of bonding between adjacent macromolecules.

The proposed model for tropocollagen (Fig. 2, 1) consists of a somewhat flexible filament of length  $c$ .

2800 Å, divided into 9 zones consisting of 5 bonding zones of length about  $0.4D$  (265 Å) separated by 4 non-bonding zones of length about  $0.8D$  (375 Å). It should be appreciated that the measurements quoted in this report represent approximate values drawn from our own experiments and other results cited in the literature.

It need not necessarily be assumed that the non-bonding regions are completely devoid of polar amino-acids. Indeed it appears from the cross-linking experiments that there is some lysine in these parts of the macromolecule. Nevertheless, it seems that in the native fibre only a few intermolecular bonds are formed between the non-bonding zones.

When tropocollagen units, conforming to the above model, are aggregated together so that there is an initial random choice as to which bonding region on one molecule cross-links in a structurally complementary manner with a bonding region on a different molecule, a fibre with 640 Å periodicity results (Fig. 2). A model of a collagen fibril constructed in this way shows a close resemblance to the structure of native collagen revealed by negative staining. Moreover, aggregation of tropocollagen macromolecules in an apparently random manner to form collagen fibrils has been observed by us in the electron microscope. There is no need to postulate a two-stage process in which tropocollagen macromolecules are first polymerized by end-to-end linkage through the interaction of terminal peptide chains to form protofibrils, which are then displaced relatively to one another by 0.25 of the molecular length (Schmitt and Hodge<sup>13</sup>; Hodge and Petruska<sup>14</sup>). Nor is it necessary to suggest an initial polymerization of tropocollagen units by overlapping which is limited to the ends of the molecules, to be followed by 'quarter staggering' of the protofibrils (Olsen<sup>15</sup>).

It also follows from the model for native collagen that all the tropocollagen units in one fibril will face in the same direction. The direction of polarization of a fibril, as determined from the band pattern, will depend on the direction of polarization of the first tropocollagen macromolecule. If, therefore, the tropocollagen macromolecules are not initially all pointing in the same direction, the resulting collagen fibrils will also be polarized in different directions. This is of interest in view of the recent finding

Fig. 2. 1. The diagram illustrates the proposed model for tropocollagen, consisting of a rather flexible filament divided into 9 zones. Five of these are bonding zones and four are considered as non-bonding zones. 2, 3. Association of tropocollagen by random aggregation through bonding zones is illustrated. The overlap between two adjacent macromolecules can cover one to five bonding zones. The direction of the macromolecules, indicated by arrows, determines the polarization of the collagen fibril. 4. The establishment of a repeat pattern of 640 Å results in the formation of light (*a*) bands as bonding zones and dark (*b*) bands as non-bonding zones. 5. For diagrammatic purposes, the linking with an (*a*) band is shown to illustrate the possible flexibility of the macromolecules.

Fig. 3. a, FLS type 1, showing repeat period of about 2500 Å. b, FLS Type 1, following treatment with glutaraldehyde. The re-establishment of the 640-Å period is clearly visible. Both preparations were negatively stained.

of Braun-Falco and Rupeo<sup>24</sup> that in human dermis the collagen fibrils have an 'antiparallel arrangement'.

More direct evidence that the tropocollagen macromolecule consists of nine segments comes from experiments on the FLS form. In Fig 3a is shown an electron micrograph of FLS Type 1, made by dialysing an acetic acid solution of collagen containing serum glycoprotein; the repeat distance is about 2500 Å while the distance measured between the outer edges of the light bands corresponds to the length of an SLS crystallite (c. 2800 Å) or tropocollagen unit. This indicates that the FLS-1 structure is formed by overlap of the terminal bonding zones of tropocollagen as suggested by Olsen. However, the reason for the formation of this type of fibre may be that adsorption of negatively charged glycoprotein on to the tropocollagen units prevents the establishment of intermolecular bonds by the intermediate bonding zones, thus producing the wide spacing (Fig. 4; 1, 2). Moreover, when such an FLS-1 preparation was treated with glutaraldehyde the 640 Å repeat period was re-established (Fig. 3b). Presumably the glutaraldehyde was able to bridge between amino-groups in the blocked bonding zones to re-establish the native period. These experiments appear to provide clear evidence of the existence of 5 similar zones in the tropocollagen molecule separated by regions having different properties. The three intermediate bonding zones in tropocollagen can thus be suppressed

with glycoprotein but revealed by subsequent treatment with glutaraldehyde (Fig. 4; 2, 3).

In the case of the SLS crystallite, negative staining has revealed a marked asymmetry of the band structure. On the other hand, although Olsen<sup>17</sup> has attempted to deduce, by photographic methods, a relationship between SLS and the native fibril, a number of points remain obscure. The band pattern observed in the SLS form may in part be due to the presence of negatively charged ATP molecules interacting with positively charged groups in tropocollagen, outside as well as within the bonding regions. If this interpretation is correct, the SLS pattern could be regarded, in part at least, as an artefact with a band structure (by negative staining) not directly related to the native fibre. Furthermore, in the case of positively stained SLS form, the staining with phosphotungstic acid or uranyl acetate undoubtedly reveals the position of basic and acidic groups in the macromolecule. Positive staining, however, does not seem to indicate whether or not these groups are involved in the formation of bonds between adjacent macromolecules.

The fundamental difference between the model proposed here and other interpretations lies in the division of the tropocollagen filament into five more or less equal bonding zones separated by four regions apparently capable of forming few intermolecular links. It should be emphasized that the bonding zones mentioned in this report have no connexion with the subunits of Petruska and Hodge<sup>25</sup>. Collagen fibres have also been observed with a repeat period of only 210–220 Å (Gross<sup>7</sup>). By assuming that, under the conditions of pH and ionic strength necessary to precipitate this form, only a portion of each bonding zone is able to interact with another, it is possible to derive this repeat period from the new model (Fig. 5). It may be noted that the short period of 210–220 Å is less than the length of a bonding zone (A band) and also one-third of the native period as would be expected if this model is correct.

This investigation has been restricted to the longitudinal and transverse structure of collagen fibres in a two-dimensional sense. Work is at present in progress to include three-dimensional (cross-sectional) aspects of the problem and a three-dimensional model is being developed. Notwithstanding that this is only a two-dimensional model, since aggregation takes place in an essentially random fashion the criteria of Smith<sup>26</sup> appear to be satisfied.

Fig. 4. 1 and 2, The establishment of a repeat period of 2500 Å by tropocollagen macromolecules aggregated in the presence of glycoprotein. Linking between intermediate bonding zones is suppressed by glycoprotein, resulting in the observed long spacing. 2 and 3, FLS 1, showing re-establishment of 640-Å period by treatment with glutaraldehyde

Fig. 5. The establishment of the observed short (210-220 Å) period is illustrated in the diagram. This can be considered to occur under conditions where each macromolecule is capable of interacting only with neighbours over a portion of the bonding zone.

We thank the Wellcome Trust for a grant for the purchase of an electron microscope and ancillary apparatus.

## FORMULATION AND USE OF EQUATIONS OF STATE FOR ELASTICO-VISCOUS LIQUIDS

By DR. K. WALTERS

Department of Applied Mathematics, University College of Wales, Aberystwyth

RHEOLOGY, which deals with the mechanics of continua, is a science which has come into prominence during the past fifteen years. Various disciplines, ranging from biology to chemical engineering, have been involved in its development. In the present communication I shall be concerned with the impact of applied mathematics on the science and I shall endeavour to trace the development of theoretical rheology. I shall direct particular attention to the study of incompressible elastico-viscous liquids, these being materials that are predominantly fluid but have some of the properties usually associated with solids. We have set ourselves no easy task, as a cursory glance of the literature will indicate, and newcomers to the field are faced with unnecessary hardships. These hardships are due to a number of factors, including the following:

(a) There is a confusing and ambiguous notation and terminology with an over-indulgence in definitions. This is perhaps best illustrated by considering a specific example. In a paper published in 1950, Oldroyd<sup>1</sup> defined certain kinematic tensors as 'rate-of-strain tensors'. Essentially the same tensors were re-derived by Rivlin and Ericksen<sup>2</sup> in 1955, and they have since become known as 'Rivlin-Ericksen tensors'. Noll<sup>3</sup> later introduced different 'rate-of-strain tensors' and Coleman and Noll<sup>4</sup> argued that Rivlin and Ericksen were the first to realize the importance of the 'Oldroyd rate-of-strain tensors'.

(b) There is a reluctance on the part of workers in the field to relate their work to what has gone before. The

result of this is that one gets the impression that theoretical rheology has had more than one beginning and one is left in doubt as to the merit of papers published before the various 'revivals'.

(c) There is often an unnecessary emphasis on mathematical rigour, and important physical principles are sometimes hidden by an abstract notation and analysis. In the present article it is hoped to show that although the development of the study of elastico-viscous liquids has been unsystematic and unnecessarily complicated, it is nevertheless possible to trace it.

The first major contribution that demands our attention is an article by Oldroyd<sup>1</sup> in 1950. In this paper, Oldroyd laid down certain principles that rheological equations of state have to satisfy. The two major principles may be stated as follows:

(i) The equations must be consistent with the requirement that the behaviour of a material element depends only on its previous rheological history and not in any way on the state of neighbouring elements.

(ii) The equations must be consistent with the requirement that the behaviour of a material element does not depend on the translatory or rotatory motion of the material as a whole in space. Although this principle was not given a name by Oldroyd, it has since become known by at least two names—'material objectivity' and 'material indifference'. The importance of this principle has been rightly emphasized by a number of later workers, who prefer to regard it as being concerned with indifference to an observer (identified with a moving co-ordinate

frame) rather than indifference to the absolute motion of the material in space (as in the formulation of Oldroyd), but the two approaches are precisely equivalent.

Oldroyd was able to satisfy the two principles mentioned here by introducing a convected co-ordinate system  $\xi^j$  drawn in the material and deforming continuously with it. This co-ordinate system has the property that a material element which is at  $\xi^j$  at time  $t$  will be at the same position (referred to the convected co-ordinate system) at all other times. There is an unlimited number of co-ordinate systems of the type envisaged here, but the equations  $\xi^j = \xi^j(\xi)$  relating two sets of convected co-ordinates  $\xi^j$  and  $\xi^j$  do not involve the time explicitly. This means that convected components of tensors associated with the same point of the material can be manipulated in the same way as the fixed components of tensors at a fixed point in space. Since principle (1) involves the consideration of a given material element over a period of time, the convected co-ordinate system is an ideal frame of reference to work with.

The convected co-ordinate system has the further advantage that it is unaffected by any superposed rigid-body motion (the co-ordinate surfaces being embedded in the material). This means that provided one works in a convected co-ordinate system and uses variables and operations which do not introduce any dependence on absolute motion in space, the resulting equations of state automatically satisfy the principle of material indifference (and principle (i), from that which was said earlier).

A suitable kinematic variable follows naturally from a description of the material properties in terms of a convected co-ordinate system. Since all quantities which refer to absolute motion in space are irrelevant, one is interested in the relative distance and the relative motion of the parts of an arbitrary element at  $\xi^j$ . The element of length  $d\xi$  between  $\xi^j$  and  $\xi^j + d\xi^j$  is given by:

$$[d\xi(t)]^2 = \gamma_{ji}(\xi, t) d\xi^j d\xi^i, -\infty < t < \infty \quad (1)$$

so that the metric tensor  $\gamma_{ji}$  of the  $\xi^j$  co-ordinate system is an obvious choice (but not the only one) as the kinematic variable. ( $t$  is taken to be the present time and  $t'$  an earlier time.) If  $D/Dt$  denotes a time derivative keeping convected co-ordinates constant, such quantities as  $D\gamma_{ji}(\xi, t)/Dt$ ,  $D^2\gamma_{ji}(\xi, t)/Dt^2$ , . . .  $D^n\gamma_{ji}(\xi, t)/Dt^n$  are also to be regarded as important kinematic quantities, these being measures of the relative motion of the parts of the arbitrary element at  $\xi^j$ .

Oldroyd took the covariant stress tensor  $\pi_{ji}(\xi, t)$  as the dynamic variable, and proceeded to develop his general theory on the basis of the variables defined here. The one disadvantage in working in terms of convected co-ordinates is that the equations of state should preferably be referred to axes fixed in space, since in any flow problem these equations have to be solved simultaneously with the familiar equations of motion and continuity. However, Oldroyd derived well-defined rules for transforming to a fixed system of co-ordinates. For example,  $\pi_{ji}(\xi, t)$ ,  $\gamma_{ji}(\xi, t)$  transform immediately into  $p_{ab}(x, t)$  and  $g_{ab}(x, t)$ , where  $p_{ab}$  is the stress tensor referred to a fixed system of co-ordinates  $x^a$  and  $g_{ab}$  is the metric tensor of this co-ordinate system; quantities such as  $(1/2)D^2\gamma_{ji}(\xi, t)/Dt^2$ , evaluated at  $t' = t$ , transform into rate-of-strain tensors  $e_{ab}^{(n)}(x, t)$ ,  $e_{ab}^{(1)}$  being the familiar (first) rate-of-strain tensor of classical hydrodynamics; quantities associated with the time  $t'$  transform into more complicated expressions involving the displacement functions  $x^a$ . For example,  $\gamma_{ji}(\xi, t')$  transforms into:

$$\frac{\partial x^a}{\partial \xi^j} \frac{\partial x^b}{\partial \xi^i} g_{ab}(x')$$

( $x^a$  is the position at time  $t'$  of the element that is instantaneously at the point  $\xi^a$  at time  $t$ .)

We have spent some time discussing Oldroyd's approach to the subject of formulation, in order to show that later contributions can in fact be regarded as applications of Oldroyd's general theory. These later contributions involve the writing down of what might seem to be appropriate equations of state relating suitable variables and the satisfying of the two principles mentioned here (the second being concerned with indifference to an 'observer') by means of well-defined mathematical rules. We might call this the 'mathematical' approach as against Oldroyd's more 'physical' approach. However, it must be emphasized that the two approaches are precisely equivalent.

The next contribution that requires consideration is a paper written by Rivlin and Ericksen<sup>2</sup> in 1955. These authors used the 'mathematical' approach to reduce a speculative equation of state into a form that satisfies the two principles mentioned here. Their initial equations were formulated on the basis that the stress is a function of the velocity gradients, acceleration gradients . . .  $(n-1)$ th acceleration gradients. Their derived equations can be effectively written in the form:

$$p_a = -pg_a + p'_a \quad (2)$$

$$p'_a = f[e_{ab}^{(1)}, e_{ab}^{(2)}, \dots, e_{ab}^{(n)}] \quad (3)$$

where  $p$  is an arbitrary isotropic pressure. From what was said earlier, it is clear that these equations could be immediately written down as a potentially useful set of equations of state from Oldroyd's general analysis. The actual merit of the work of Rivlin and Ericksen would therefore appear to be in the prominence the work has given to the useful equations of state given by (2) and (3), rather than in the formulation procedure used by these authors.

Later work by Rivlin<sup>3</sup>, and Rivlin and Spencer<sup>4,5</sup>, on the theory of matrix (tensor) polynomials can be regarded as a useful extension of the work of Rivlin and Ericksen.

In 1958, Noll<sup>6</sup> demonstrated that modern mathematics (particularly 'Functional Analysis') can be used with success in the formulation of equations of state. His initial work was concerned with systematizing the 'mathematical' approach and with the introduction of a very general class of fluids known as 'simple' fluids. In the notation of Oldroyd, these are defined by:

$$\pi'_{ji}(\xi, t) = \mathcal{F} [\gamma_{ji}(\xi, t')] \quad (4)$$

in convected co-ordinates, and:

$$p'_{ab}(x, t) = \mathcal{F} [G_{ab}(x, t')] \quad (5)$$

in fixed co-ordinates, where  $\mathcal{F}$  is a 'functional' and  $G_{ab}$  is given by:

$$G_{ab} = \frac{\partial x^m}{\partial x^a} \frac{\partial x^r}{\partial x^b} g_{mr}(x') \quad (6)$$

It is again apparent that although Noll's approach is different from that of Oldroyd, the same physical principles are involved in both, and either can be used to introduce the 'simple' fluids. In some ways, the Oldroyd approach has certain advantages in this respect.

Coleman and Noll<sup>7,8-11</sup> have given detailed consideration to the 'simple' fluids and have been remarkably successful in extending Noll's earlier work. For example, they have shown how the complicated equations of state given by (2) and (5) degenerate into manageable forms when the fluid has a fading memory and the flow is slow. They have also shown that it is possible to solve a limited number of flow problems in the general case.

The work of Coleman and Noll must be regarded as a very significant contribution to the subject. However, some of the importance of their work is to some extent

masked by an over-indulgence in definitions, axioms and theorems and an over-emphasis on mathematical rigour.

Many of the rheological flow problems of practical importance cannot be handled using the general equations of Rivlin and Ericksen and Coleman and Noll. It has therefore been necessary (see, for example, refs. 12 and 13) to construct simple equations of state that give an approximate description of observed behaviour and yet are simple enough to be useful in general flow problems. These equations must, of course, satisfy the general formulation principles. In this way, theoreticians have been able to supply experimentalists with a qualitative picture of rheological behaviour (see, for example, refs. 14-20). In favourable circumstances they have been able to predict important flow characteristics which have since been observed in the behaviour of real fluids. This line of research is therefore to be thought of as a practically useful extension of the formulation work discussed earlier.

Although there has been no systematic development in the study of isotropic elastico-viscous liquids, it is nevertheless true to say that the subject has reached a satisfactory stage of development. Notwithstanding the criticisms mentioned earlier, the problem of formulation

is now resolved; and the main avenues of present-day research involve the application of thermodynamic principles and wave propagation theory to rheology and the solution of flow problems of practical importance, the latter being more a problem in differential equation theory than anything else.

I thank Dr. R. H. Thomas for advice.

## APPARENTLY SPONTANEOUS DECARBOXYLATION OF INDOLYL-3-ACETIC ACID

By DR. B. J. DEVERALL

Department of Botany, Imperial College of Science and Technology, London

**D**URING experiments on the metabolism of indolyl-3-acetic acid (IAA) in diseased plants, the breakdown of IAA was found to occur rapidly in the absence of plant tissues under some conditions in solutions of phosphate buffer at pH values between 4.5 and 5.3. This article describes some of the phenomena observed and shows how to avoid the problem. Breakdown was measured by the release of  $^{14}\text{CO}_2$  from carboxyl- $^{14}\text{C}$  labelled IAA using a similar technique to that described by Daly and Deverall<sup>1</sup>, in whose experiments spontaneous decarboxylation was negligible.

Radioactive IAA was prepared by Dr. G. W. Kirby, Department of Chemistry, Imperial College, from indole-acetonitrile- $1\text{-}^{14}\text{C}$  supplied by the Radiochemical Centre, Amersham, Bucks. Ascending chromatography of the IAA on Whatman No. 1 paper in either isopropanol/ammonia/water (85:10:15) or sodium chloride/acetic acid (100 of 8 per cent wt./vol. in water: 1) revealed one major radioactive peak, which gave a pink-purple colour after dipping in Ehrlich's reagent (1 of 10 per cent *p*-dimethylaminobenzaldehyde w/v in conc. HCl:4 of acetone) and had the same  $R_F$  as unlabelled IAA from L. Light and Co., Ltd. The ultra-violet absorption spectra of ethanolic solutions of radioactive and unlabelled IAA were identical. For experimental use, the IAA peak was eluted by ethanol from chromatograms developed in isopropanol, ammonia and water, and the eluate plus a few drops of ammonia were evaporated to dryness. The residue was dissolved in ethanol and double glass distilled water to give an ethanol concentration of 0.4 per cent. The solution was kept at  $-20^\circ\text{C}$ , in the dark, and exposed only for thawing and pipetting.

To 'Pyrex' brand beakers (3½ in. tall × 2 in. diam.) without spouts, 4.5 ml. of 0.1 M 'AnalaR'  $\text{KH}_2\text{PO}_4$  or appropriate mixtures with 'AnalaR'  $\text{Na}_2\text{HPO}_4$  were added. Flat nickel-plated mild steel planchets, 1 in. diam., containing disks of lens paper and 0.1 ml. 10 per cent KOH to capture  $^{14}\text{CO}_2$ , were suspended from rubber bungs. The planchets lay 1 in. above the base of the beakers. At the

start of the reaction, 0.5 ml. IAA solution was added to the buffer, and the vessels were transferred to a platform shaker moving at 100 strokes/min under a light-proof cloth at  $20^\circ\text{--}22^\circ\text{C}$ . Planchets were replaced when necessary, and dried at  $70^\circ\text{C}$  for 1 h before counting while hot in an Ekco sample oven beneath an end-window Geiger-Müller tube coupled to an Ekco scaler. Initial radioactivity of IAA in the reaction mixtures was obtained from 0.1 ml. aliquots pipetted on to 0.1 ml. 10 per cent KOH and lens paper in planchets. Thus all samples were counted at standard thickness and for 300 sec, and the decarboxylation expressed as a percentage of the counts from the IAA- $^{14}\text{C}$  appearing as  $^{14}\text{CO}_2$ .

The problem of the decarboxylation became apparent during a series of experiments using new beakers and tomato stem tissues. The beakers were routinely washed in hot mains water and glass-distilled water, but had received one overnight soak in a chromate cleaning solution followed by copious water washings and soaks. Table 1 shows the effect of pH on decarboxylation. Each replicate beaker contained 10 µg/ml. IAA, supplying 0.5 µg.

Excessive liberation of  $^{14}\text{CO}_2$  in the first hour was a pronounced feature of the reaction. All parts of the reaction system were checked to find the cause. First the same beakers were used after further water washing, and the effects of ethanol and unlabelled IAA, which was used to make up the concentration of IAA, were tested at pH 4.5. Results are given in Table 2.

Clearly the addenda were not the cause of the trouble. The competitive effect of unlabelled IAA and the surprising inhibitory effect of ethanol were recorded.

The glassware and the water used to make up the reaction mixtures were then tested for their effects on the stability of IAA.

Table 3 summarizes the results of experiments on the effects of treatments applied to the surface of the beakers used to obtain the results in Table 1 and which had been exposed to chromate once in their history. Glass-distilled water was used in these tests.

Table 1. EFFECT OF pH ON CUMULATIVE DECARBOXYLATION OF IAA

Time (h)	4.5	pH 4.7	5.3	6.0
1 h	18.7%*	17.3%	2.7%	0.6%
3 h	19.4%	18.1%	4.3%	0.9%

\* Initial radioactivity of IAA per beaker = 17,000 c.p.m.

Table 2. EFFECT OF ETHANOL AND UNLABELLED IAA ON CUMULATIVE DECARBOXYLATION OF IAA

Time (h)	Labelled IAA*	Labelled IAA* in 0.04% ethanol	Labelled IAA* in 0.04% ethanol plus unlabelled IAA†
1 h	6.4%	4.9%	5.6%
3 h	16.1%	10.9%	6.6%

\* 1.66 µg/ml. supplying 18,000 c.p.m. per beaker

† 10 µg/ml. giving final IAA conc. of 11.66 µg/ml.

Table 3. EFFECTS OF GLASSWARE TREATMENTS ON THE STABILITY OF IAA

Series*	Glassware treatments	Decarboxylation % - 1st h
I	H <sub>2</sub> O	13.4
	dichromate/H <sub>2</sub> SO <sub>4</sub>	21.4
	1N HCl	18.5
	1N HNO <sub>3</sub>	17.8
	1N NaOH	16.0
II	dichromate/H <sub>2</sub> SO <sub>4</sub> --- NaOH	1.9
III	hot 10% methanolic NaOH	30.0
IV	celloidin membrane	1.5

Reaction mixtures - 1.6 µg/ml. IAA at pH 4.5

\* I - 3 h soak in sol., repeated rinses in water and 1 h soak in water.

II - 18 h soak in sol., repeated rinses in water, 40 min soak in 0.1 N NaOH and further water rinses.

III - 10 min in sol. and repeated rinses in water.

IV - Rinse in sol. celloidin in ether and few drops ethanol, dried and rinsed in water.

Therefore further treatment with chromate accentuated the subsequent instability of IAA. Several treatments with acids and alkali were worse than mere water soaking, and the disastrous effect of methanolic NaOH is evident. However, removal of chromate by dilute NaOH using a recommended technique<sup>1</sup> or separation of IAA from the glass by a celloidin membrane greatly increased the stability of IAA.

Comparison of different types of water to make reaction mixtures showed that IAA was equally stable in single and double glass-distilled water and in water from a metal still. However, ion-free water from a laboratory ion-exchange demineralizer stimulated decarboxylation to 18.9 per cent in the first h when tested as part of series II in Table 3.

Finally, tests were performed on new 'Pyrex' brand beakers. Table 4 shows the stability of IAA in lots of glassware, which differed only in length of storage from manufacture to use, and which were prepared by washing in hot 'Stergene', hot mains water and double glass distilled water before drying at 90° C. Batches of the newest beakers from the warehouse of James A. Jobling and Co., Ltd., Sunderland, and sent by Mr. F. C. Sedgwick were also subjected to different desirable pretreatments which he suggested.

Table 4. EFFECT OF NEW BEAKERS AND THEIR PRE-TREATMENT ON THE STABILITY OF IAA

Source of beakers	Pre-treatment	Decarboxylation % - 1st h
College stores - old stock	'Stergene', H <sub>2</sub> O and 90° C	1.5 - 2.5
College stores - new stock	" " "	1.5 - 2.5
Factory warehouse	" " "	0.9
Factory warehouse	and repeated use and soaking in H <sub>2</sub> O	0.8
Factory warehouse	autoclaved (inverted) for 1 h at 121° C*	0.9
Factory warehouse	warm 5% acetic acid*	1.5
Factory warehouse	and "overnight" soaking in H <sub>2</sub> O	0.6

Reaction mixtures - 1.0 µg/ml. IAA at pH 4.5 (double glass-distilled water).

\* Then rinsed in water, acetone, drained and dried at 90° C.

Percentage decarboxylations obtained in the newest glassware after water washing or soaking were comparable to those recorded by Daly and Deverall<sup>1</sup>, who worked at 15° C and used solutions supplemented with labelled IAA to give final concentrations of 10 µg/ml. The greater instability of IAA in beakers which had been stored for longer periods and during a London winter may be attributable to the deleterious effects of atmospheric pollutants on glass surfaces.

Therefore, when working with IAA at pH values of 4.5-5.3, it is necessary to check glassware, which may have been chemically contaminated in storage or in prior use, and to avoid cleaning solutions which may damage the glass surface or be difficult to remove. Glass-distilled water may be preferable to ion-free water.

This work was supported by a grant from the Agricultural Research Council.

## THE BRAIN OF THE HETEROSTRACI (AGNATHA)

By DR. H. PHILIP WHITING

Department of Zoology, University of Bristol  
AND

DR. L. B. HALSTEAD TARLO

Department of Geology, University of Reading

BENEATH the dorsal headplate of the heterostracan group of palaeozoic agnathan fishes there are often impressions which appear to represent the dorsal surface of the brain; a number of neural features have been described, particularly of cyathaspid Heterostraci, from this evidence. The structures revealed usually include an identifiable pineal organ, anterior and posterior semi-circular canals, and some dorsal areas of the brain, as shown in Fig. 1, which is based on illustrations of *Foraspis polaris* and *Homalaspisidella* (*Homalaspis*) *nitida* by Kiaer and Heintz<sup>1</sup>.

The cyathaspids were very early and so presumably very simply organized vertebrates. A modern brain with which this one might be compared would then be that of the lamprey (compare Goodrich<sup>2</sup>), or that of the primitive shark *Heptanchias* (compare Johnston<sup>3</sup>) which is seven-gilled, as were probably the cyathaspids<sup>4</sup>. But the brain of the larval or pride stage of the lamprey, shown in Fig. 2, is perhaps more suitable: as Watson has pointed

out<sup>5</sup>, the Heterostraci probably passed through a larval stage in which they would resemble the pride in many respects.

Several attempts to identify the regions of the heterostracan brain have been made, in particular those of Stensiö; his account of 1958 may perhaps be regarded as the definitive one<sup>6</sup>. The most recent is that of Denison<sup>7</sup>, who has made brief but useful comments on the brain in the course of a general description of cyathaspids. Interpretations differ, and it is possible that they have been made from too small a factual basis, but we consider that the visible regions can be identified safely if the comparative evidence is assessed.

Some non-skeletal tissue probably formed at least part of the impressions, for the roof of the chondrocranium in lower vertebrates is separated from the brain by wide tissue-spaces and may itself have extensive fontanelles, so that the roof could only give impressions of brain-shape in quite localized areas. Now in cyclostomes, the sur-

viving Agnatha, the meningeal envelope around the brain is simple: there is a compact meninx primitiva adhering closely to the brain; outside the meninx is a thick perimeningeal zone containing mucoid cells<sup>7</sup>. The impressions may therefore have been made at the boundary between meninx and perimeningeal tissue, where there would be considerable chemical and physical differences between the two tissues, or partly at the outer surface of the perimeningeal tissue, adjacent to skeletal parts<sup>8</sup>. Certainly the distinction between nervous tissue and choroid plexus, which shows up in the hind-brain region especially, would be difficult to account for on a basis of impressions made by skeletal parts alone, and indeed there seems little reason to suppose there was extensive internal cartilage in Heterostraci.

The medulla oblongata extended as far forward as the level of the junction between the anterior and posterior semi-circular canals, where the VIIIth nerve enters the brain; it is unlikely to have extended further forward, as will be seen later. The medulla is rather elongate, and tapers slowly towards the spinal cord; this is probably related to the large number of gills innervated by the Xth nerve, six as in the lamprey, for these involve a longer extent of the visceral components within the central nervous system. The central dorsal area evidently represents a choroid plexus, which would extend in life above the dorsal limits of the medulla, but might either collapse or fail to be preserved in fossil material (compare Kiaer and Heintz, Plate 30, ref. 3, with Goodrich's figure). The area of the hind-brain plexus is narrower than in lampreys, suggesting that there was a smaller concentration of grey matter here than in the lampreys; if so, the cyathaspid medulla was less developed and retained a greater resemblance to the spinal cord.

The otic capsules would closely surround the system of semi-circular canals; the horizontal canal if it existed would not be viable, but it is generally believed to be absent, since it is not developed (from the anterior canal) in modern Agnatha. The capsules extend forward as far as the caudal part of the mid-brain as they do in the adult lamprey. In the pride stage the capsules are very delicate; a similar condition in the Heterostraci would account for the canals, and not the capsules, forming the surface which provides the impression in the otic region.

The cerebellum in the lamprey is little more than a small transverse commissure of the VIIIth and lateralis components. In cyathaspids it is difficult to discern this region. There may have been a small cerebellar commissural band or merely a narrow choroidal 'neck' joining the

larger choroidal areas of the mid- and hind-brains: the latter would be a more primitive condition.

The mid-brain appears to have been like that of the larval and adult lamprey, retaining a central choroidal plexus; this is a stage through which the mid-brain passes in the development of jawed fishes. The condition is strongly indicated not only in Stensio's figures but also, for example, in those of Kiaer and Heintz of *Poraspis polaris*. This region has been identified by Kiaer and Heintz as mid-brain, and possibly by Stensio in Fig. 205A; but elsewhere Stensio identifies this rounded region with its flat centre as a part of the hind-brain, for example, Fig. 180.

The conformation of the visible parts of the mid- and hind-brain is then similar to that of the lamprey except for the apparent absence of a short hind-brain region in front of the VIIIth nerve. Tentatively, this difference would be explained very satisfactorily if the dorsal pre-otic nerves, that is V<sup>1</sup>, V<sup>2+3</sup> and VII, entered the brain dorsal to the corresponding somatic motor nerves III (and IV) and VI, that is, in what is believed to be their primitive cranial position, so that at least the trigeminal roots came from the mid-brain wall and not that at the front of the hind-brain. However this may be, the identity of the mid-brain seems unmistakable.

Turning to the fore-brain, the exposure of the brain-roof, between the mid-brain and the pineal complex, is longer than in most vertebrates. The diencephalon of the lamprey is also long, the pineal and parapineal organs extending forward from their origins in the pair of habenular ganglia. But the diencephalon of *Hepttranchias*, as illustrated by Johnston, has a roof that is remarkably like that of cyathaspids, and it has the symmetrical form that the lamprey, like many fishes, lacks.

The telencephalon (end-brain) is not visible in front of the diencephalon. Stensio has suggested that the front of the brain was sharply down-turned and so the end-brain would not be visible in the impressions: he pointed out that young myxinoids have a cephalic flexure of this sort. But in hagfishes this flexure is embryonic and is lost by the time of hatching<sup>9</sup>. Denison remarks that it is logical to assume that the pineal organ "lay, as in lampreys, at the anterior end of the diencephalon, and that the telencephalon lay antero-ventrally to it. There is no evidence that the fore-brain was crowded as in embryonic myxinoids, as claimed by Stensio (1958, p. 374)". In Stensio's reconstruction-figures, however, the end-brain is shown, not down-turned but strongly fore-shortened, and pushed back to either side of the diencephalon, while the rest of

the brain is elongate. His figure therefore follows the brain of the lamprey, and not that of the hagfish, where the whole brain is extraordinarily compressed. The compression in the lamprey is brought about by its nasohypophyseal system: in the pro-ammo-coete stage, where this system has not moved back and come to press on the brain, the end-brain still extends anterior to the diencephalon, as measured along the axis of the notochord<sup>10</sup>.

So it seems that compression antero-posteriorly, of either type, that of lamprey or hagfish, is not to be expected in cyathaspids. Stensio's reconstructions (Figs. 200 and 209) would raise many problems, particularly the whereabouts of the diencephalon and the identity of the constricted area of brain in front of the otic capsules, which is not indicated in these figures, although it is shown in figures of actual specimens, for example, Fig. 206.

We believe that the end-brain lay directly anterior to the diencephalon. The end-brain of *Hepttranchias* may be used for comparison: it is one of the least specialized

Fig. 1

Fig. 2

known among vertebrates, retaining a large telencephalon medium around the median ventricle. This end-brain has been drawn on the right in Fig. 1 (dotted white); at this scale the diencephala in the fossil and the living form are almost coincident in roof pattern. The olfactory system has also been drawn from *Hepiranchias*, although the length of the olfactory tract, which of course varies greatly, has not been copied; the position of the olfactory capsules in Heterostraci is not known precisely, but the capsules are sited by most workers in the position shown.

If the end-brain lay in this position it would not necessarily leave a clear impression; this would depend on whether the dorsal surface were nervous, as in *Hepiranchias*, or choroidal, and on the nature of the overlying tissues. There would apparently be room for the end-brain below the dorsal shield in this position; this can be seen from Denison's Fig. 105. In cyathaspid material, a trough, in the position where the end-brain of *Hepiranchias* would lie, has frequently been observed, for example, in Stensio's Fig. 205A. This may well be the impression of the telencephalon: the area of this trough is indicated by shading in Fig. 1.

So there seems good reason to suppose that cyathaspids, which are among the earliest vertebrates known, possessed, not a specialized, but on the contrary a very primitive form of brain. The brain was as primitive as that of the

pride but lacked the epithalamic asymmetry and compressed form of end-brain found in the latter. The brain of cyathaspids, and presumably also of other Heterostraci, may have been more primitive than that of any surviving vertebrate in its hind-brain organization: the anterior region of the hind-brain does not yet appear to have been built up dorsally by the caudalward migration of the pre-otic dorsal roots towards the post-otic dorsal roots. This migration must certainly have occurred during early vertebrate phylogeny; the condition in cyathaspid fossils may indicate where it occurred. We have previously pointed out that the somites of the pre-otic region were also organized in a more primitive manner than in any living vertebrate<sup>11</sup>.

## TAIL TO TAIL AGGLOMERATION OF BULL SPERMATOZOA BY PHYTOAGGLUTININS PRESENT IN SOY-BEANS

By PROF. TAKAO KASHIWABARA, RYOICHI TANAKA and TAKUYA MATSUMOTO

Department of Animal Breeding, Faculty of Agriculture, Ibaraki University, Tsuchiura, Japan

IT has been known for a long time that extracts of certain plant seeds (lectins) agglutinate erythrocytes of human as well as of animal origin. Many workers have shown that certain leguminous lectins are specific for certain blood group factors in human beings and chickens<sup>1-4</sup> and have demonstrated their usefulness in practical blood typing<sup>5</sup>. It has been previously demonstrated that mammalian spermatozoa exhibit antigenic characteristics in the identification of blood-group antigens in man and the bull or in the agglutination test of spermatozoa by antisera<sup>6-12</sup>. Sperm agglutination is a very general phenomenon, but any investigations of the action of natural heteroagglutinins on mammalian spermatozoa would be of interest in relation to spontaneous infertility in cattle and selective fertilization of animals if one were found that was specific for spermatozoa (see Tyler's discussion of the relation between immunological phenomena and fertility control<sup>14,15</sup>).

Experiments were designed to investigate the action of plant (soy-beans) extracts on fresh bull spermatozoa and were planned along the same lines as agglutination tests in blood grouping. Saline extracts of 21 strains of soy-beans, including 'Glycine max(L.)' and 'Glycine ussuriensis', were used. The procedure for extracting the lectin from soy-beans was a modification of that described by Boyd *et al.*<sup>16</sup>, and Leister and Kirk<sup>17</sup>. A 5-g sample in 2 volumes of saline was refrigerated for two nights and then thoroughly ground. The pulp was filtered through gauze, and centrifuged at 4° C for 15 min to remove debris. After the supernatant had been heated in a 100° C water bath for 30 min, the mixture was centrifuged and the final supernatant used in the test for the lectin. Sperm suspensions for the agglutination test were obtained by suspending artificially collected bull spermatozoa in 100 volumes of sterile saline. These were examined microscopically as well as macroscopically

30 min after mixing with equal volumes of lectins at room temperature (23°-25° C) using an agglutination slide for serology.

1,103 tests were carried out on the agglutinating effects of 21 soy-bean lectins on spermatozoa from 92 cattle. In 362 cases the spermatozoa showed a specific tail type of agglutination (Fig. 1). Spontaneous head-to-head agglutination of spermatozoa is a very general phenomenon and can be shown *in vitro* by saline dilution of mouse, horse, or fowl spermatozoa (it occurs less readily with bull spermatozoa). The present tail-to-tail type of agglutination is different from the head-to-head type of agglutination, and the tails of bull spermatozoa, which are highly motile, agglomerate in clumps showing a rim of heads on the outside in the suspension with soy-bean lectins. This tail-to-tail agglutination of bull spermatozoa

Fig. 1. X-type reaction of bull spermatozoa, tail-to-tail agglutination of sperm by phytoagglutinins of soy-bean. Phase contrast ( $\times 200$ )

resembles a 'three-dimensional cart wheel' and is similar to hetero-sperm agglutination in *Katharina tunicata*<sup>18</sup>, agglutination of bull spermatozoa in an antiserum<sup>19</sup>, tail agglutination of *Megathura orenulata*<sup>19</sup>, and agglutination of animal sperm with the normal sera<sup>20</sup>. This type of bull spermatozoa agglomeration, which occurs when a sperm suspension is mixed with soy-bean lectins, is a very simple  $Z_I$ -type agglomeration, does not occur spontaneously and is distinguishable from other complicated types of agglomeration or agglutination ( $Z_{II}$ ,  $Z_{III}$ , etc.)<sup>21</sup> observed in the test using other plant lectins, for example, from (*Phaseolus angularis*, *Ricinus communis*, etc.). It has been proposed that these tail-to-tail agglomerations should be called  $Z$ -type agglomeration, from the German *Zusammenball*, thus directing attention to their specificity without confusing them with usual agglutination<sup>18,19-20</sup>.

It was of interest to find that  $Z_I$ -agglomeration of spermatozoa did not occur in every sample of bull semen, but that it was individual-specific, and even breed-specific (Table 1). Some lectins specifically agglomerated sperms of Holstein-Friesian.  $Z_I$ -positive reactions occurred in 38 per cent of the Holstein-Friesian samples, 17 per cent Black Japanese (work cattle) and 11 per cent Brown Japanese (work cattle). In Table 1 the more interesting data are also shown as a percentage of the bulls tested whose spermatozoa reacted, but for which the results are not statistically significant (due to the small number of animals used).

Table 1.  $Z_I$ -TYPE AGGLOMERATION OF BULL SPERMATOZOA OBSERVED USING SOY-BEAN LECTINS

Breeds of cattle	% Tested bulls whose spermatozoa react			% Tests that show positive reactions		
	No. of bulls tested	Positive bulls	% positive	No. of total tests	$Z_I$ -agg.	% of $Z_I$ -positive
Holstein-Friesian (H)	68	48	70.6	808	312	38.6
Black Japanese (B)	12	6	50.0	106	18	17.1
Brown Japanese (R)	9	4	44.4	90	10	11.1
Jersey (J)	2	0		12	0	
Brown Swiss (BS)	2	0		5	0	
Total	92	58		1,020	340	

Statistical tests:					
	H	B	R		
No. positive bulls	48	6	4	No. positive reactions	18 10 312
No. negative bulls	20	6	5	No. negative reactions	87 90 496
Total bulls	68	12	9	Total tests	106 90 808
$\chi^2 = \begin{Bmatrix} 1.97 & 0.06 \\ 2.48 & \\ 25-10 & 90-75 \\ 25-10 & \end{Bmatrix}$					
$P: \begin{Bmatrix} 25-10 & 90-75 \\ 25-10 & \end{Bmatrix}$					

The lectins of soy-beans were found to be breed-specific in  $Z_I$ -positive reaction (Tables 2 and 3). It was interesting to find that soy-bean lectins showed almost entirely  $Z_I$ -type agglomeration (340  $Z_I$ -positive and only 12  $Z_{III}$  in 1,020 tests). The detailed results of  $Z_{III}$  reactions will be presented later. It has been suggested that the reaction of human blood with peanut lectin could be used in population studies<sup>22</sup>, so the present reaction with the soy-bean lectins could be useful for grouping bull sperm—especially if one were established that was specific for spermatozoa.

Further investigations are being made of the mechanism of sperm agglomeration, and of the chemical properties, including a molecular analysis, of the lectins. It may be noted that spermatozoa are observed only in motile conditions and disappear 2 h after the beginning of the test. Our present observations suggest that the agglutinins of the seed extracts may be of a protein nature and heat-stable. It would also seem possible that the lectins can be divided into a number of groups.

We thank the Ibaraki Agricultural Experiment Station and the National Institute of Animal Industry for the gifts of seed used in these investigations and the National Breeding Station of Livestock-Fukushima, Local Live-

## CIRCADIAN PERIODICITY IN SOME PHYSICO-CHEMICAL PARAMETERS OF CIRCULATING BLOOD

By DR. G. V. F. SEAMAN, PROF. RUDOLF ENGEL and PROF. ROY L. SWANK

Department of Medicine, University of Oregon Medical School, Portland

AND

DR. WOLFGANG HISEN

Department of Surgery, University of Heidelberg

THE view that an organism maintains physicochemical parameters at specific levels has impeded studies of their oscillatory nature and obscured the aims of some laboratory investigations. Endogenous rhythms of approximately 24 h duration have been termed 'circadian' by Halberg<sup>1</sup>. Circadian rhythms continue under adverse environmental conditions such as reversal of the light regimen or sleeping habits. A routine work schedule should synchronize the endogenous circadian rhythm with the 24-h scale. These circadian rhythms characterize a number of basic cellular processes as well as the endocrine and neural controls of functional co-ordination in time<sup>1,2</sup>. Halberg<sup>1</sup> has documented the role of a circadian adrenal cycle in the maintenance of external timing.

In man it has been shown that temperature<sup>3</sup>, blood volume and haematocrit<sup>4,5</sup>, total serum protein<sup>6,7</sup>, circulating blood cells and certain electrolytes and steroids<sup>8</sup> exhibit circadian rhythms. Circadian changes in the erythrocyte sedimentation rate remain debatable<sup>9</sup>.

In the present study a number of related physicochemical parameters have been measured at standard time intervals in order to determine the extent to which they exhibited a circadian rhythm. An appreciation of the oscillatory nature of the viscosity of blood and levels of certain components of the plasma may lead to a re-evaluation of the significance of 'normal values' and clarify some aspects in the periodicity of host-parasite relationships as exemplified by the cycle of microfilariae in the peripheral blood.

Three male volunteers participated in the study for a period of 72 h. (R.E. 59, 155 lb.; R.S. 55, 136 lb.; W.H. 27, 180 lb.) and one female (B.E. 26, 121 lb.) for two 24-h cycles. The volunteers were in bed from midnight until after the 0800 sample had been taken and were asleep at the time of withdrawal of the 0400 sample. The oral temperatures of the subjects in °F were measured just before each venepuncture. Blood samples (20 ml.) were collected in heparinized syringes at 4-h intervals. The times indicated under results represent midpoints covering a period of about 20 min. Subjects were fasting for the 0800 samples, meals being taken at 08.30, 1200, tea 1500, and 1800. Varying degrees of lipaemia were present in the plasma samples.

Screen filtration pressures were determined as described by Swank<sup>10</sup> and Swank, Roth and Jansen<sup>11</sup> immediately after sampling. Erythrocyte sedimentation rates in mm/h were obtained using Wintrobe tubes and these were then spun at 2,000g for 40 min to determine the haematocrit.

Coefficients of viscosity for each sample of blood were determined at shear rates of 2.30, 5.80, 11.5, 23.0, 46.0 and 115 sec<sup>-1</sup> in a Brookfield micro cone-plate viscometer maintained at 25.0 ± 0.1°. The viscometer was equipped with a torsion spring giving full-scale deflexion at 336 dynes cm and a standard spindle (cone-plate angle 1.57°, diameter 4.8 cm).

Calcium, potassium and sodium ions were estimated by means of a Beckman 'DU' spectrophotometer with a flame attachment and photomultiplier<sup>12</sup>, the procedures and calculations being performed as previously described<sup>13</sup>. Total plasma proteins were determined by the biuret method of Weichselbaum<sup>14</sup> and also, in the case of reasonably non-lipemic samples, with a Bausch and Lomb serum protein meter<sup>15</sup>. Protein-bound sialic acid was determined in the

trichloroacetic acid-insoluble fraction of plasma, using Svennerholm's resorcinol reagent<sup>16</sup>. Protein-bound carbohydrate was estimated using the phenol-sulphuric acid colorimetric method<sup>17</sup> adapted to the trichloroacetic acid-insoluble fraction of plasma with a mixed standard of 1:1 galactose mannose. Plasma-bound hexosamines were assayed by the procedure of Winzler<sup>18</sup>.

The withdrawal of 20 ml. blood every 4 h limited the extent of sampling in single individuals. It was assumed that the pooling of simultaneous observations on four individuals (mean of the population sample mean) over a period of about 72 h is equivalent to a theoretically continuous period of two weeks on a single individual (overall sample mean). The closer the mean of the population sample mean corresponds to the overall sample mean the more probably is this procedure valid. After withdrawal of the regular 0800 specimen on the last day of the experiment, two of the subjects engaged in special physical exercise by running and climbing stairs so as to observe the effect of strenuous muscular activity on the values of the physico-chemical parameters.

The circadian rhythm of temperature and of total plasma protein in relative values is shown in Fig. 1. The overall sample mean value for oral temperature was 97.63° F and the mean of the population sample mean 97.64° F; accordingly 97.6° F corresponds to 100 per cent. The range varied between 96.6° F and 98.6° F. Statistical analysis gave an *F* ratio of 2.079 with *P* = 0.021. Total plasma protein levels followed a similar course, with overall and population sample means of 8.42 g per 100 ml. The *F* ratio was 5.232, *P* < 0.001. Protein-bound carbohydrate and hexosamine levels follow the total protein rhythm. The overall sample mean value for hexosamine was 80.08 mg, the population sample mean 79.87 mg and the range from 65.1 mg to 98.2 mg per 100 ml., *F* ratio 5.170, *P* < 0.001. The overall sample mean value for protein-bound carbohydrate was 119.5 mg per 100 ml., and the mean of the population sample mean was 119.7 mg per 100 ml. The range varied between 102 and 135 mg, *F* ratio 3.919, *P* < 0.001.

Plots of the means of screen filtration pressure and also erythrocyte sedimentation rate against time suggested visually the presence of a circadian rhythm. However, the individual differences, and hence the standard deviations of the pooled samples, were too great for evaluation of significance by variance analysis and therefore detailed documentation is omitted.

Total protein, protein-bound carbohydrate and hexosamine levels were at a minimum between midnight and 0400. Haematocrit and sialic acid (Fig. 2) showed similar minima, but the maxima occurred at 0800, a few hours before the peak in total protein, protein-bound carbohydrate and hexosamine. Protein-bound sialic acid (Fig. 2) had an overall sample mean value of 45.7 mg per 100 ml. and mean of population sample mean of 45.6 mg per 100 ml. with a range from 36.8 to 60.3 mg, *F* ratio 2.37, *P* = 0.0085. The haematocrit had an overall sample mean value of 44.2 with a mean of the population sample mean of 44.1. The values varied between 41.0 and 48.5 (Fig. 2). The *F* ratio was 2.52, *P* = 0.0053.

Plots of the relative circadian changes in viscosity of blood at all shear rates have been superimposed and graphic representation of the standard deviations omitted

for clarity. Analysis of variance gave  $P < 0.001$  in all cases. The range of percentage change from the mean decreased with increasing shear rates as follows:

Shear rate in  $\text{sec}^{-1}$ : 2.30, 5.80, 11.5, 23.0, 46.0, 115.

Range of relative percentage difference from mean: 62-136, 79-123, 86-121, 87-114, 89-116, 91-112.

Changes in the concentration of calcium, sodium and potassium ions did not show a circadian rhythm in whole blood, in plasma or in the values calculated for red cells. Any changes that might have occurred in the distribution of cations would be masked because the time required for the cations to exchange with the extravascular compartments is brief in comparison with the time required for significant circadian changes to occur in an associated parameter such as the blood volume.

The values of blood viscosity and levels of total protein, protein-bound carbohydrate, hexosamine and sialic acid in plasma follow, not unexpectedly, in view of their

Fig. 1. A transverse profile on four subjects relating variations over a 72-h period in temperature, total plasma protein, hexosamine, and protein-bound carbohydrate. The data are plotted as relative change, per cent of mean, and the standard deviation is indicated. The mean is given in absolute values. Midnight is marked by 00 and a vertical line; noon by 12. The number of pooled samples is indicated at 4-h intervals on the time axis.

Fig. 2. A transverse profile on the same four normal adults relating variations over the 72-h period in sialic acid, haematocrit and whole blood viscosity. The data are plotted as relative change, and per cent of mean. Viscosity is measured in centipoises at six specific shear rates as indicated by the numbers ranging from 2.30 to 115  $\text{sec}^{-1}$ . In the figure for blood viscosity the plotting of standard deviations has been omitted because of overlapping.

relationship to blood volume, the known course of circadian changes in haematocrit<sup>6</sup>. It is likely that the fluctuations in the physicochemical parameters arise in part from the rapid transference of water from the peripheral circulation into other compartments as a result of the changes in posture and muscular activity which occur from day to night. Venous stasis of a limb, for example, leads to a general exchange of water in the body<sup>10</sup>. The increases observed in these parameters, following additional exercise, support the hypothesis of the rapid transfer of water.

However, there is also an underlying endogenous periodicity. Renbourn<sup>7</sup> has reported a significant decrease in plasma protein-level after 22.00 h which is independent of bed rest, and Bartter, Delea, and Halberg<sup>8</sup> have shown that the diurnal elevation of urinary aldosterone cannot be explained solely on the basis of haemodynamic changes.

The elevation in temperature and blood viscosity during the initial period of the observations is attributable to normal subjects showing a greater variation than usual because of anxiety ('novelty effect'). Once the daily routine was established even the perturbation produced by the venepuncture at 4-h intervals was normally without significant effect on the circadian rhythm. Amplification of the changes in the physicochemical parameters occurs

if an enhancing procedure such as exercise is carried out during the endogenous rises at the time of arousal.

The individual variation in the screen filtration pressure was too great to enable any quantitative assessment of circadian periodicity in this parameter. The screen filtration pressure depends on a number of variables, including concentration of blood elements, plasma constituents and, in particular, adhesiveness and aggregation of platelets, leucocytes and red cells. The white cell count is known to exhibit a circadian cycle mediated by the activity of the adrenal gland. In man the lowest white cell counts occur during the day<sup>22</sup>, which would favour low values for the screen filtration pressure, whereas the plasma protein-levels and haematocrit tend to be high at that time and thus nullify this effect.

Again, the erythrocyte sedimentation rates which depend on haematocrit, rate of aggregation of the red cells, composition of the plasma, electrical charge on the cells, etc., showed no direct circadian periodicity. It was not considered feasible to correct the erythrocyte sedimentation rates for the effects of circadian variations in the values of the associated parameters.

Maxima in the value for the viscosity of blood are better synchronized with the peaks in concentration of protein-bound sialic acid than with the peaks of total protein-bound carbohydrate. Sialic acid is largely responsible for the electrokinetic charge carried by circulating blood cells, especially erythrocytes<sup>23</sup>, and also in part for the charge and rheological behaviour of many glycoproteins. The fluctuation in levels of sialoproteins in the blood may affect the value of the electrokinetic charge borne by circulating cells and endothelial surfaces and thus influence the cycle of such parasites as microfilariae. The 24 h rhythms in *Wuchereria bancrofti* microfilariae and blood eosinophils have been compared by Engel, Halberg, Dassanayake and de Silva<sup>24</sup>. These organisms are known to accumulate in the lungs during the day, being released

again at night. If the microfilariae are constrained in the lung capillaries by electrostatic forces, physicochemical changes mediated by the circadian variation in the level of sialoproteins could lead to changes in the electrical charge carried either on the filariae or wall of the capillary and thus to the release of the microfilariae into the peripheral circulation again.

Although the fluctuations in many of the physicochemical parameters are largely attributable to 'activity potentiated' changes in haemodynamics there remain endogenous rhythms for which the nature of the mechanism of the ultimate controlling system, or 'master biological clock', is unknown at present.

## DENSE RANDOM PACKING OF BINARY MIXTURES OF SPHERES

By PROF. S. YERAZUNIS, S. W. CORNELL and B. WINTNER

Department of Chemical Engineering, Rensselaer Polytechnic Institute, Troy, New York

A NUMBER of investigations of the properties of dense random packing of spheres have been reported recently. McGeeary<sup>1</sup> has presented experimental packing density measurements for binary mixtures and maximum packing densities for ternary and quaternary mixtures. Benenati and Brosilow<sup>2</sup> investigated the local void fraction distribution for single-size spheres over a large range of aspect ratio, that is, container-to-sphere diameter ratio. Yerazunis, Bartlett and Nissan<sup>3</sup> proposed a theory for the packing of binary mixtures based on a distortion mechanism. The present work was undertaken to obtain more definitive data with which to test this theory.

The desired amounts of the two classes of spheres, in excess of that which could be accommodated by the final container, as determined by weight, were mixed carefully and poured into a 'Lucite' cylinder, 63 mm in diameter and 63 mm in height. A second cylinder of the same diameter but of smaller height, 50 mm, was joined and sealed with tape to the first cylinder. The mixing device so formed was tumbled extensively to homogenize the mixture. With the device oriented vertically and the sphere mixture in the smaller of the cylinders, the system was vibrated to maximum density using the actuator from a door-bell mechanism. In order to avoid too intense a vibration and the concomitant low-density packing, the actuator and the impact surface were arranged to obtain a subtle, mild action. The effectiveness with which the dense random packing was achieved is suggested by the measured packing fraction for single-size spheres of

0.635–0.639, a range which corresponds rather well with the extrapolated value of 0.637 reported by Scott<sup>4</sup>. Two min vibration proved sufficient to compact mixtures of the smaller size, but vibration was extended to 5 min for mixtures involving a large-size class. After compaction the cylinders were separated and the surface of the compacted mixture in the smaller of the cylinders was levelled using a stiff sharp-edged steel rule. The excess mixture was separated and the weight of the larger spheres in the excess was determined. The packing fraction and the composition of compacted mixture in terms of fraction of occupied volume were calculated from the initial weights charged, the compacted weight and volume of the smaller cylinder, the weights of excess spheres and the densities of the two sizes of spheres involved. The diameter ratios investigated, together with the diameters of the spheres employed, are summarized in Table 1. The experimental data are shown in Fig. 1, in which are also shown the data obtained by Atkins and Barriah<sup>5</sup> for the diameter ratio of 12.

Previous investigations<sup>1,2,6</sup> have revealed that the packing fraction of mixtures of spheres is greater than

Table 1

Diameter ratio	Diameter (mm)	
	Large spheres	Small spheres
180	15.83	0.068
67.7	5.95	0.068
5.74	0.50	0.068
3.41	0.297	0.038
2.58	0.297	0.115

that of either single class and exhibits a maximum value, which is a function of diameter ratio, in the neighbourhood of 0.73 volume fraction large spheres. This general behaviour can be explained in terms of two models, one applying to the range of large-sphere concentrations up to the critical value corresponding to the maximum packing density, the other to the remaining concentration range. Consider for the moment a dense random array of small spheres. The addition of a large sphere results in the displacement of the equivalent volume of small spheres and increases the overall packing fraction by eliminating the micro-voids associated with the small-sphere régime which was replaced. This replacement process may be continued up to that point at which the large spheres are themselves arrayed in dense random packing. Starting with the opposite extreme, small spheres can be added to an existing random array of large spheres by the filling of existing voids. The procedure may be continued until the macro-voids formed by the large spheres are entirely filled by small spheres.

In the case of an infinite diameter ratio, the small-sphere régime will be characterized by a void fraction corresponding to dense random packing in a container of infinite aspect ratio and the packing fraction-composition function can be predicted theoretically. However, for finite diameter ratios, the distortion of the small-sphere régime due to the large-sphere surfaces must be taken into account for compositions of large spheres below that corresponding to maximum packing density. Beyond this point, two factors present themselves. Starting with a large-sphere array, small spheres can be introduced into sufficiently large macro-voids without disturbing the large-sphere arrangements. At some composition determined by the sphere diameter ratio, the macro-voids large enough to accommodate small spheres will become saturated. Further additions of small spheres can be effected only by expanding the large-sphere lattice.

This investigation has been concerned with the behaviour of mixtures of spheres for compositions less than

that corresponding to the maximum packing fraction. The observed behaviour can be explained as follows. In the binary mixture, the small spheres can be imagined to occupy domains of size and shape determined by the number of large spheres per unit volume and their arrangement. On average, the volume of a small-sphere domain will be given by  $(1 - V_1 N_1)/N_1$ , where  $V_1$  is the volume of a large sphere and  $N_1$  is the number of large spheres per unit volume. A length characteristic of the size of the small-sphere domain can be defined  $D_s$  equal to  $[(1 - V_1 N_1)/N_1]^{1/3}$ . Accordingly, a measure of the local aspect ratio, that is, particle-to-domain dimension, is  $[D_1/D_s]/(1 - V_1 N_1)^{1/3}$ , where  $D_1$  is the diameter of the small sphere.

Scott's investigation provides a basis on which to relate the packing fraction of the small-sphere domain,  $f_p^\infty$ , to the aspect ratio by:

$$f_p^\infty = f_{p^\infty} - K D_s [N_1 / (1 - V_1 N_1)]^{1/3} \quad (1)$$

where  $f_{p^\infty}$  is the packing fraction for dense random arrays of equal spheres in an infinite container and  $K$  is an empirically determined constant.

Since the degree of distortion of the small-sphere domains from the infinite aspect ratio configuration would be expected to be related to both the aspect ratio and the extent of 'wall' (surface of large spheres), equation (1) must be modified. On average, one large sphere is associated with each small-sphere domain. It is proposed that an effective packing fraction,  $f_{p^\infty}$ , be defined so as to reflect the area of the large sphere relative to a sphere of diameter corresponding to the characteristic domain dimension,  $D_s$ , that is, a function of  $[D_1/D_s]^2$ . The simplest assumption is to replace  $K$  in equation (1) by  $K' [D_1/D_s]^2$ , with the result that:

$$f_{p^\infty} = f_{p^\infty} - K' (D_1/D_s)^2 D_s [N_1 / (1 - V_1 N_1)]^{1/3} \quad (2)$$

Since the packing fraction for the mixture,  $f_p$ , is:

$$f_p = V_1 N_1 + (1 - V_1 N_1) f_{p^\infty} \quad (3)$$

equations (2) and (3) can be combined with the expression for domain dimension to yield:

$$f_p = V_1 N_1 + [1 - V_1 N_1] \left\{ f_{p^\infty} - K' D_s^2 \frac{N_1}{1 - V_1 N_1} \right\} \quad (4)$$

Noting that  $V_1 N_1 = f_{p^\infty} y$ , where  $y$  = fraction of large spheres in the occupied volume, equation (4) can be rewritten as:

$$f_p = \frac{f_{p^\infty}}{1 - (1 - f_{p^\infty} - \frac{6K'D_s}{\pi D_1})y} \quad (5)$$

The question which now requires resolution is whether the distortion parameter,  $K'$ , is dependent on the relative curvatures of the small and large spheres. The experimental measurements obtained in this study indicate that the distortion parameter is related to the diameter ratio through:

$$K' = 0.165 (D_1/D_s)^{-2.164} \quad (6)$$

Equation (6) is to be interpreted as an indication that the distortion of the small-sphere régime is reduced with decreasing large- to small-sphere diameter ratio. The concept is not only in keeping with one's intuition but also with the fact that in the limit of a diameter ratio of unity, where the addition of one sphere involves only a simple replacement, there is zero distortion. Unfortunately, equation (6) does not extrapolate to this limit as is noted later; however, it does describe the phenomenon over the range of diameter ratios investigated.

Substituting (6) in (5):

$$f_p = \frac{f_{p^\infty}}{1 - (1 - f_{p^\infty} - 0.315 [D_1/D_s]^{0.766})y} \quad (7)$$

Equation (7) was used with  $f_{p^\infty} = 0.638$  to obtain a comparison with the experimental data. The agreement was quite good over the range of diameter ratios studied, with the exception of some deviation for the 3.41 diameter ratio for compositions exceeding 0.5 volume fraction and more substantial disparity for the 2.58 case above a composition of 0.3.

Fig. 1. Packing fractions in binary mixtures. Lines represent theoretical values derived from equation (11). Point symbols represent experimental data.

Some indication as to the reason for this behaviour is obtained by noting that the number of small spheres per domain corresponding to the composition at which the experimental results depart from the theoretical expectations is approximately 40 in both instances. The average domain dimension expressed in terms of small bead diameters is somewhat over six. As the concentration of large spheres is increased, the size of the small-sphere domain is reduced even further. In the case of the 5.74 : 1 mixtures, the 40 to 1 ratio of small to large spheres is reached only at a composition of 0.82, which is beyond the maximum packing fraction point. It is proposed that the distortion parameter defined by equation (6) is not adequate for small-sphere domains of less than 40 spheres and that the following relationship is more suitable:

$$K' = A[D_s/D_l]^m + B[N_l/N_s] \quad (8)$$

The first term on the right-hand side of (8) is the correction for the effect of curvature on the distortion parameter which was described earlier. The second term is proposed as an empirical approximation to the effect of domain size expressed in terms of number of small spheres per large sphere.

The ratio of large to small spheres can readily be expressed in terms of diameter ratio and composition as:

$$N_l/N_s = [D_s/D_l]^3[y/1-y] \quad (9)$$

Equations (5), (8) and (9) are combined to produce the final relationship between packing fraction, diameter ratio and composition:

$$f_p = \frac{f_{p\infty}}{1 - [1 - f_{p\infty} - \frac{6}{\pi} A(D_s/D_l)^{1+m}y - \frac{6}{\pi} B(D_s/D_l)^4y^3/1-y]} \quad (10)$$

The optimum values of the correlating constants were determined to be:  $A$ , 0.165,  $m$ , -0.294 and  $B$ , 0.5.

The numerical equation actually used then was:

$$f_p = \frac{0.638}{1 - [0.362 - 0.315(D_s/D_l)^{0.706}y + 0.955(D_s/D_l)^4y^3/1-y]} \quad (11)$$

At this point it should be noted that the constants  $A$  and  $m$  in the expression (8) for the distortion parameters are believed to be reasonably reliable because of the number of data points available for test. The correction for domain size is less confidently known. The form chosen in (8) satisfies the requirements that this term should be

negligible for larger diameter ratios and for low compositions. It is by no means the only formulation which could fit the available experimental data. Accordingly, the recommendation made above should be regarded with some restraint as but one possible representation. Additional experimental data will be required before a more positive conclusion can be reached. On an overall basis, equation (11) correlates the experimental findings quite adequately as shown by the comparison between theoretical and experimental results in Fig. 1.

The predicted packing fraction-composition curve for the infinite diameter ratio is obtained by letting  $[D_s/D_l] \rightarrow 0$  yielding:

$$f_p = \frac{0.638}{1 - 0.362y} \quad (12)$$

The difference between predictions for the infinite ratio and for the largest ratio studied experimentally, 180 : 1, is quite small as one might reasonably expect. It is to be noted that the model (12) predicts a concave upward curve for the infinite ratio case which is in contradiction to the linear relationship which had previously been proposed in (3) and (6). It would appear that the latter conclusion may have occurred as a consequence of oversimplification of the replacement mechanism.

Although the proposed model and the final expression, (11), fit the available data and lead to the expected results for the very high diameter ratio, they do not extrapolate effectively in the opposite direction. For the case of mixing equal-sized but otherwise distinguishable spheres, the packing fraction should be independent of composition. Equation (11) clearly does not satisfy this asymptotic requirement. The problem to be faced with small diameter ratio of the order of two or less is that the domain size expressed as the number of small spheres per large sphere reaches the critical value of the order of 40 at very low concentrations of large spheres. Under these conditions, the distortion parameter formulation defined (8) would appear to be entirely inadequate.

## STRONTIUM ISOTOPE INVESTIGATION OF IGNEOUS ROCKS FROM ICELAND

By DR. S. MOORBATH

Department of Geology and Mineralogy, University Museum, Oxford

AND

DR. G. P. L. WALKER

Department of Geology, Imperial College of Science and Technology, London, S.W.7

THE limited range of variation in the initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio of basaltic rocks (particularly in oceanic areas) suggests that the source regions of basalts are relatively homogeneous with respect to their Rb/Sr ratios<sup>1,2</sup>. The average Rb/Sr ratio in the sialic crust is substantially higher than in the source regions of basalt<sup>3-5</sup>. On this basis, Faure and Hurley<sup>1</sup> suggested that there is sufficient enrichment of strontium-87 (resulting from the radioactive decay of rubidium-87) in crustal materials to use the  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio of igneous rocks, at time of crystallization, as a criterion for the origin of the material. Thus the

initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio of an igneous rock formed by remelting of—or contamination with—ancient crustal material may be expected to be measurably higher than that of an igneous rock formed by differentiation of basaltic magma.

Strontium isotope measurements are reported in this article for a small, but reasonably representative, set of basic and acid igneous rocks of Tertiary to Recent age from a number of localities in Iceland (Fig. 1). The rock-types include gabbro, basalt, andesite, basaltic acid tuff, pitchstone, obsidian and granophyre. Most of

the specimens were collected by one of the authors (G. P. L. W.), but those from the Snafrudal intrusion were collected by A. E. Beswick.

Iceland exhibits many features of unusual geological interest, not least its situation astride the mid-Atlantic ridge, as well as the large-scale, intimate association of basic and acid igneous rocks. The problem of the origin of the acid igneous rocks is of considerable interest. Carmichael<sup>6</sup>, in his investigation of the crystallization of feldspar from volcanic acid liquids, considers those Icelandic rhyolites and pitchstones which he has examined to belong to that class produced by the fractionation of tholeiitic magma. On the other hand, Walker<sup>7</sup> states that "such large amounts of acid (and intermediate) magma seem unlikely to have originated by crystal fractionation of basaltic magma and that a sialic crust seems a more likely source. Recent seismic work in western Iceland by Tryggvason and Baath<sup>8</sup> has, however, failed to reveal a layer that can be identified as sial, and direct evidence for the existence of a sialic crust below eastern Iceland is lacking; but it may be that the great abundance of acid material in the Icelandic central volcanoes is evidence of its existence." According to Cargill *et al.*<sup>9</sup> and many later workers, no floor of sial is visible anywhere in Iceland, no 'accidental' xenoliths have been discovered in lavas or intrusions, nor blocks in the volcanic piles; nor is there any evidence in the petrological character of the rocks of the assimilation of sedimentary material.

Strontium isotope measurements were carried out with an A.E.I. MS-2 mass spectrometer with a 60°, 6-in. radius analyser tube and an electron multiplier as the ion-beam detector. A single tantalum-filament, surface ionization technique was used. Full experimental details have been described elsewhere<sup>10,11</sup>. In order to eliminate unpredictable isotopic fractionation effects, all measured  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios were normalized to  $^{87}\text{Sr}/^{86}\text{Sr}=0.1194$ , in line with the procedure adopted by other workers<sup>1,2</sup>. This also has the effect of improving the reproducibility of replicate measurements. The average  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio found in the course of the present work was 0.1183, nearly 1 per cent below the conventional value of 0.1194. It appears, however, from the work of Hedge and Walthall<sup>3</sup>, that the single filament ionization technique can yield slightly lower  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios than triple filament ionization. A check on reproducibility was provided by

Fig. 2. Histogram of initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios from Iceland

frequent isotopic analysis, during the course of the work, of the Eimer and Amend strontium carbonate standard, circulated internationally by the Massachusetts Institute of Technology group. The mean of eight separate measurements of the  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio was 0.7076, with a standard deviation of  $\pm 0.0010$ . In the 1964 report of the Massachusetts Institute of Technology group<sup>12</sup> it is stated that the normalized values found by several other laboratories for the Eimer and Amend  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio lie between 0.7075 and 0.7085. It is considered that in the present work the reproducibility of a single  $^{87}\text{Sr}/^{86}\text{Sr}$  measurement is  $\pm 0.0015$  at the 66 per cent confidence-level.

Rubidium and strontium determinations were made by X-ray fluorescence analysis, yielding values to at least  $\pm 10$  per cent. The lower detection limit for rubidium was about 5 p.p.m. The Rb/Sr ratio and the geological age of the rocks were too low to necessitate an age correction in the measured  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios.

Measurements were carried out either on powdered, whole rock specimens, or on plagioclase feldspar separates.

The results of strontium isotope measurements, expressed as the normalized, initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios, are given in Table 1. Fig. 2 is a histogram of the results. It is evident that, with one exception, there is no significant difference in the  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio between any of the rocks so far measured. The mean value for twelve basic rocks (omitting P. 673, see following) is  $0.7024 \pm 0.0009$  and for eleven acid rocks  $0.7016 \pm 0.0008$ . (Six of these acid rock samples are from the same rock unit, see following.) A single andesite measurement yields  $0.7020 \pm 0.0015$ ; this sample has an appreciable Rb/Sr ratio, but even on the assumption of a maximum age of 50 million years, the  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio would only decrease to 0.7022.

The basalt lava P. 673 (No. 7, Table 1) from Breiddalur gives the only 'anomalous' strontium isotope result, with an  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio of  $0.7089 \pm 0.0010$ , representing the mean of two separate determinations. The rock does not appear in any way unusual, but it occurs in an unusual geological environment. It occupies the caldera or crater of the Tertiary Breiddalur central volcano, described by Walker<sup>1</sup>. Below, and separated from it by one other lava flow, is a thick hyaloclastic accumulation, the result of subaqueous eruption of basalt into the lake which occupied the caldera. It appears unlikely that the water was sea-water. (Since the  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio of sea-water is about 0.708, soaking of the lava in sea-water and resulting element and isotope exchange could account for the comparatively high  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio of the basalt.) However, fumaroles and hot springs are thought to have contributed to the lake, and the rocks now visible beneath the basalt lava consist mainly of highly altered rhyolites and acid pyroclastics, which might have been the source of the slight excess of  $^{87}\text{Sr}$ .

\* Determined by X-ray fluorescence, n.d. = not detectable.

† Normalized by adjusting <sup>86</sup>Sr/<sup>86</sup>Sr to 0.1194 and the measured <sup>87</sup>Sr/<sup>86</sup>Sr ratio by half this amount. The figure in parentheses after the ratio indicates the number of analyses performed for each specimen.

K/Ar age on sample A. 39 whole rock is 6.5 ± 1.1 million years (analysis, D. C. Rex).

Of the acid rocks, the six samples from the Slaufudal granophyre stock (Nos. 19-24, Table 1) of Eastern Iceland are of particular interest. This is the largest known intrusive mass in Iceland, with an outcrop covering an area of 15 km<sup>2</sup> and with a volume of at least 10 km<sup>3</sup>. The structure and petrology of this intrusive have been described by Cargill *et al.*<sup>9</sup>, and further details will be published elsewhere by A. E. Beewick. Although many of the principal plutonic intrusions of Eastern Iceland are composite masses, mainly composed of gabbro, granite and granophyre, the Slaufudal stock consists of acid rock only. A potassium-argon determination on whole rock sample A. 39 yielded an age of 6.5 ± 1.1 million years. Even allowing for a plausible maximum of about 20 per cent loss of argon from potash feldspar, this puts the age of intrusion of the stock very late in the Tertiary. This unexpectedly young age explains why the <sup>87</sup>Sr/<sup>86</sup>Sr ratios all agree within the limits of experimental error, despite the fact that the Rb/Sr ratios of the six samples range from 0.4 to 2.3.

Samples No. 16, 17 and 18 (Table 1) are feldspar crystals obtained from interbasaltic acid tuff horizons. These tuffs are the products of explosive eruptions of acid magma, during which feldspar phenocrysts became separated from the acid magma. Being in a protected environment, surrounded by soft and loose tuffaceous material, these crystals are usually free from fractures and in a very fresh condition.

The well-known postglacial obsidian from Hrafninnhryggur (No. 25, Table 1) was first described and chemically analysed by Wright<sup>13</sup> and later by Carmichael<sup>14,15</sup>.

The strontium isotope results suggest that these relatively few acid rocks from Iceland so far investigated are ultimately derived from the same source region as the basic rocks, presumably the upper mantle. The acid rocks were formed either by the fractional crystallization

of basic magma<sup>6</sup> or by some process of partial melting of basic rocks. The possibility that they were produced by the partial or complete remelting of an ancient sialic crust beneath Iceland with anything like the average crustal Rb/Sr ratio is excluded by the isotopic data. If such a crust exists—and there is no direct evidence for it—then, either, it has not contributed any significant amounts of material to the acid rocks investigated in this study, or it is not older than about 100 million years. Clearly, many more strontium isotope measurements on Icelandic rocks are needed. However, if none of the acid rocks is found to contain a significant enrichment of strontium-87 over basalt, it would provide rather strong circumstantial evidence for the absence of ancient, sialic crust beneath Iceland. The presence or absence of such a crust would have an important bearing on reconstructions of the northern land masses prior to (hypothetical) continental drift. It is inherent in the present interpretation of the isotope results that there is some mechanism by which comparatively large volumes of acid magma can accumulate at depth by derivation from the same source regions as basalt magmas, or from basalt magma itself. This may have happened at various times during the Tertiary geological history of Iceland.

It is of interest that the average <sup>87</sup>Sr/<sup>86</sup>Sr value for the Icelandic rocks is significantly lower than for the basic rocks of at least some of the continental areas of the North Atlantic Tertiary igneous province. An average value of 0.7058 ± 0.0010 has been reported for basic rocks from the Isle of Skye, north-west Scotland<sup>11</sup>, while the average value for the basic rocks of the Skaergaard intrusion, East Greenland, is 0.7065 ± 0.002<sup>16</sup>. However, the mass spectrometer used in the present study gave an average <sup>87</sup>Sr/<sup>86</sup>Sr value for the Eimer and Amend standard which is about 0.0020 lower than that obtained with the mass spectrometer used in the Skye and East Greenland investigations. (There is something to be said for correct-

ing the measured  $^{87}\text{Sr}/^{86}\text{Sr}$  from all laboratories to an agreed value of this standard.) Nevertheless, even allowing for instrumental differences, there still appears to be a significant difference of about 0.002–0.003 between the Iceland results and those from Skye and East Greenland.

This difference is in accord with the findings of previous workers<sup>1,2</sup> that the  $^{87}\text{Sr}/^{86}\text{Sr}$  values for oceanic basalts are, on the whole, slightly lower and less variable than those of continental basalts. Hedge and Walthall<sup>3</sup> report an average of 0.703 for oceanic basalts, while two Recent basalts from Iceland measured by them gave an average of 0.7025. The values for continental basic volcanic rocks appear to lie in the range 0.702–0.710<sup>1,2</sup>.

It was mentioned above that the high  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio of  $0.7089 \pm 0.0010$  for the Breiddalur basalt, P.673, might be due to some superficial process such as leaching and isotopic exchange. Nevertheless, the possibility must be kept in mind that this is a true, primary ratio, indicating local inhomogeneities in the Rb/Sr ratio of the basaltic source regions. More work is in progress on this problem. It is of interest to note that Faure and Hurley<sup>4</sup> reported a single  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio of  $0.7101 \pm 0.0004$  for a Recent olivine basalt of unspecified locality from Iceland. These authors have recently revised all their originally published  $^{87}\text{Sr}/^{86}\text{Sr}$  values downwards by about 0.003, but in either case the quoted value is close to that of the Breiddalur Tertiary basalt. Clearly, the suspicion is justified that not all the basic rocks of Iceland have  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios as low as 0.702–0.703.

It is important not to carry the analogy between the acid igneous rocks of Iceland and of the Tertiary igneous centres of north-west Scotland too far. While there may be some general similarities in field relationships and mode of occurrence, the ultimate origin of the granitic material may be quite different in the two cases. This emerges already from recent investigations of the feldspars in certain volcanic acid liquids by Carmichael<sup>5</sup>, as well as from geochemical and trace element studies on natural acid glasses from the North Atlantic Tertiary province by the same author<sup>14,15</sup>. Indeed, Carmichael<sup>14</sup> considers that "the acid magma available for eruption in Iceland, as represented by the pitchstones, shows little variation

in composition throughout perhaps as much as 60 million years".

The general uniformity of the Iceland strontium isotope results contrasts strongly with the results from two large Tertiary plutonic igneous centres in the Isle of Skye, north-west Scotland, where it has been shown<sup>11</sup> that the initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios of granitic and related rocks are significantly higher (about 0.713) than those of nearby basaltic rocks. This suggested that the granitic and related rocks were produced by partial melting of ancient Lewisian rocks (>1,600 million years) which form the underlying basement at no great depth in Skye. This interpretation was in agreement with conclusions drawn from other recent, totally independent, experimental lines of evidence<sup>6,17</sup>.

There are clearly several ways in which granitic magma can be formed, even within a single volcanic province. It is to be hoped that strontium isotope investigations, in addition to the more conventional geological, geochemical, petrological and mineralogical criteria, will provide a clue to the mode of origin in any particular case.

We thank our colleagues for their advice. The work at Oxford forms part of the programme of age and isotope studies directed by Prof. L. R. Wager.

## FORMATION OF OCEANIC RIDGES

By DR. M. H. P. BOTT

Department of Geology, University of Durham

OCEANIC ridges form an interconnected system of underwater mountain ranges about 80,000 km in total length (Fig. 1). They stand 2–4 km above the average depth of the oceans and vary in width from a few hundred to four thousand kilometres. They form the largest uplifted surface feature of the Earth. This article suggests a mechanism for their uplift.

It has recently been shown that the East Pacific Rise was formed by uplift of the sea-bed from normal oceanic depths during the Tertiary<sup>1</sup>. The Mid-Atlantic Ridge was also probably formed during the Tertiary<sup>2</sup>. Menard<sup>3</sup> has shown that the atolls and guyots scattered over a substantial area of the north-west Pacific were originally volcanoes reaching sea-level on the crest and flanks of a Mesozoic ocean rise (the Darwin Rise) which has since subsided to normal ocean depths.

A similar type of uplift has affected some continental regions. Much of the western United States has been uplifted nearly 2 km since the Eocene<sup>4</sup>, forming a continental extension of the uplift which formed the East Pacific Rise<sup>5,6</sup>. This uplift is particularly well displayed in the Colorado Plateau, which remained close to sea-level from before the Cambrian until the early Tertiary and was

afterwards uplifted without folding. A similar situation appears to exist where the Indian Ocean Ridge passes into the part of Africa and Arabia which shows evidence of strong epeirogenic uplift.

Thus vertical movements of 2-km amplitude have affected vast areas of ocean floor and more restricted (but still quite substantial) areas of continent in extension of the ocean ridges. It has been widely suggested that mantle convection currents upwelling beneath the ocean ridges may indirectly provide a mechanism for the formation of the ridges and for their elevation. I support this hypothesis and further suggest that dilatation accompanying partial fusion in the rising convection current provides a direct explanation of the uplift. The evidence and arguments favouring this hypothesis are stated here.

It is inconceivable that vertical movements of 2-km amplitude can have affected regions of large areal extent without a change in density in the underlying rocks adequate to maintain approximate isostatic equilibrium. Otherwise these regions would have isostatic anomalies of more than 200-mgal magnitude either now or before the uplift occurred. Nowhere are widespread isostatic

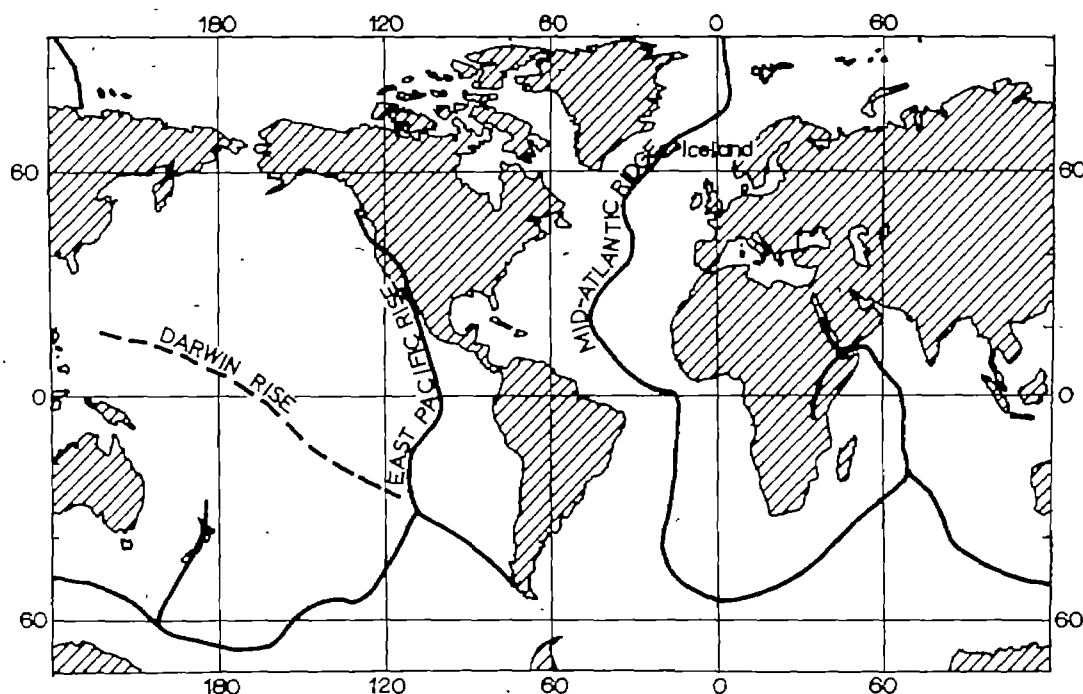

Fig. 1. System of oceanic ridges

anomalies of this magnitude known: in particular the western United States<sup>6</sup> and the oceanic ridges<sup>7,8</sup> are in approximate isostatic equilibrium despite small local departures. It also seems out of the question that regions such as the Colorado Plateau were out of isostatic equilibrium by  $-250$  mgal from the Cambrian until the Eocene unless the mantle was very much stronger then. Thus uplift and subsidence have occurred in isostatic response to substantial changes in the density of the underlying rocks.

Seismic refraction profiles show that changes in crustal thicknesses are inadequate to explain the uplift of the East Pacific Rise<sup>1</sup> (Fig. 2), or the subsidence of the Darwin Rise<sup>2</sup>, or the present elevation of the Mid-Atlantic Ridge<sup>4</sup>. The region of anomalously low density causing the elevation is therefore within the upper mantle beneath. Support for this conclusion comes from the relatively low-compression wave velocities in the topmost mantle beneath the Mid-Atlantic Ridge<sup>3,9</sup>, part of the East Pacific Rise<sup>3</sup>, Iceland<sup>9</sup> and the western United States<sup>10</sup>, since low seismic velocities normally correspond to low densities.

A region of relatively low density in the upper mantle could be attributed either to chemical inhomogeneity or to changed physical conditions causing dilatation of otherwise normal upper mantle rocks. Chemical inhomogeneity could result from a crust-mantle mix<sup>11</sup> or from variation in the proportion of minerals such as plagioclase<sup>12</sup>. Possible explanations depending on changed physical conditions include thermal expansion, silicate mineral phase changes, partial fusion and serpentinization of olivine<sup>13</sup>. Thermal expansion seems to be inadequate to produce sufficiently large changes in density<sup>13,14</sup>. If it is assumed that a single process is of dominant importance, four disconnected pieces of evidence enable a tentative choice to be made between the remaining hypotheses. These are: (1) the gravimetry and seismology of Iceland<sup>14</sup>; (2) the epeirogenic and reversible character of the uplift; (3)–(4) the inadequacy

of silicate phase changes and reactions to produce a sufficiently large density contrast. These are discussed in turn as follows:

(1) Iceland lies on the Mid-Atlantic Ridge. The average Bouguer anomaly is about  $+15$  mgal<sup>15</sup>. If the upper mantle beneath were normal, this would mean that the crust is continental (30–35 km thick). However, seismic studies in Iceland<sup>14,9</sup> suggest that the crust is only about 17 km thick and has a high average  $P$  velocity. Combining these observations, we conclude that the upper mantle beneath Iceland possesses an anomalously low density which contributes a gravity anomaly of about  $-250$  mgal. This could be caused by a reduction in density of  $0.03$  g/cm<sup>3</sup> extending over a vertical thickness of at least 225 km, or  $0.3$  g/cm<sup>3</sup> over at least 23 km. Further evidence of critical importance comes from Tryggvason's<sup>9</sup>

Fig. 2. Topographic and crustal structure profile across the East Pacific Rise, showing also the heat flow and the sub-Moho seismic  $P$ -velocity. Reproduced from an article by H. W. Menard<sup>1</sup> in *Science*, 128, 1741 (December 9, 1960), with permission.

discovery that compression wave arrivals from distant earthquakes arrive about 1.3 sec late at Reykjavik. Tryggvason interprets this delay as caused by an anomalously low compression wave velocity of 7.4 km/s extending to a depth of 200 km below Iceland. Most common rocks show an empirical relation between compression wave ( $P$ ) velocity and density, such that reduction in  $P$  velocity from the normal upper mantle value of 8.2 km/s to 7.4 km/s would correspond to a reduction in density of more than 0.1 g/cm<sup>3</sup>. Spread over a vertical extent of 200 km, this would cause a mass deficiency more than three times as large as the observed value. This suggests that the region of low density is not caused by common rock types with relatively low density. This rules out a crust-mantle mix, serpentine and phase changes in common silicate minerals, although it is possible that an unusual chemical composition could explain the discrepancy. The simplest explanation is that partial fusion causes the mass deficiency, since this would reduce the  $P$  velocity relatively more strongly than the density as the rigidity modulus vanishes on fusion.

(2) Menard<sup>3</sup> has suggested that the uplift of oceanic rises is reversible. Furthermore, there is no evidence to suggest that equal vertical movements in the opposite sense affect the adjacent belts of ocean floor during the uplift or subsidence of an oceanic rise. These considerations suggest that uplift occurs as a result of dilatation within the underlying upper mantle and that subsidence accompanies contraction to normal volume; this is difficult to reconcile with the hypothesis of chemical inhomogeneity.

(3) Experimental observations on solid-solid silicate phase transitions likely to be of importance in the topmost 200 km of the mantle show that the phase boundaries follow gradients within the range 17°–35° C/km (ref. 17). Yoder and Tilley show the basalt-eclogite transition with a gradient of about 50° C/km (ref. 18). Suppose the temperature of the upper mantle were raised by 100° C. The phase boundaries would move to greater depths by 2–6 km. If the aggregate change in density caused by all such phase changes were 0.3 g/cm<sup>3</sup>, this would cause a negative gravity anomaly within the range –25 to –75 mgal, which would only be capable of causing an uplift of 0.7 km at most. Thus solid-solid silicate phase transitions appear to be inadequate as a complete explanation of the cause of uplift, unless the upper mantle temperatures are raised excessively.

(4) Another possibility is that olivine is hydrated to give low-density serpentine. This reaction cannot occur much above 500° C. The geothermal gradient of Iceland<sup>10</sup> is such that temperatures of 500° C almost certainly occur at a shallower depth than 10 km. Similar considerations apply to regions of anomalously high flow of heat on the East Pacific Rise and the Mid-Atlantic Ridge. This raises a serious difficulty for the serpentinization hypothesis.

The foregoing considerations (1)–(4) together suggest that partial fusion is probably the dominant cause of the low-density region in the upper mantle beneath oceanic ridges and their continental extensions. It remains to demonstrate the feasibility of this hypothesis.

Experiments by Daly<sup>11</sup> show that basalt undergoes a reduction in density of about 10 per cent, or 0.3 g/cm<sup>3</sup>, on fusion. The fused fraction of an ultrabasic parent rock would almost certainly undergo a similar reduction in density. Suppose 10 per cent of the parent rock undergoes fusion, then the overall reduction in density is 0.03 g/cm<sup>3</sup>. Thus 10 per cent partial fusion extending over a vertical range of 150 km would explain the uplift of an oceanic ridge 2 km high, or a continental uplift of about 1.4 km. Partial fusion causes reduction in density by dilatation, causing uplift without the necessity of contemporaneous subsidence nearby. We now require a mechanism for causing partial fusion on this scale.

Partial fusion of the upper mantle can be caused by reduction in the confining pressure provided the initial

temperature is near to the melting point. Reduction in pressure can occur by: (1) stress release in a static mantle; or (2) progressive reduction of confining pressure in an uprising mantle convection current. Both processes depend critically on the fusion gradient, which is about 6.5°–10° C/kbar or 2°–3° C/km. This is an order of magnitude higher than the adiabatic gradient and an order of magnitude lower than the conduction temperature gradient observed at the Earth's surface.

I make the simplifying assumption that a two-phase boundary separates a liquid phase and a single solid phase (Fig. 3 shows a fusion zone). During reduction of pressure  $p$ , material initially on the phase boundary is constrained to remain on the boundary until fusion is complete. Consequently the temperature ( $T$ ) is reduced by  $(dT/dp)_i \cdot \Delta p$ , where  $\Delta p$  is the reduction of confining pressure. Under adiabatic conditions in the field of the solid or liquid phase the reduction in temperature is given by  $(dT/dp)_s \cdot \Delta p$ , where the suffix refers to the adiabatic gradient. The excess cooling resulting from the steeper fusion gradient provides the latent heat of fusion,  $L_f$ . If the appropriate specific heat is  $c$ , assumed the same for both phases, the fractional amount of fusion,  $f$ , is given approximately by:

$$f = \left\{ \left( \frac{dT}{dp} \right)_i - \left( \frac{dT}{dp} \right)_s \right\} \cdot c \cdot \Delta p / L_f$$

In a static mantle the vertical principal pressure is the weight of the overburden, which is fixed in value at a given depth. Release of confining pressure can only come about through reduction of horizontal pressure. The amount of pressure reduction is limited by the strength of the upper mantle which probably does not exceed 200 bars. If both horizontal principal pressures are reduced by 200 bars, the confining pressure is reduced by 133 bars. This would cause a lowering of temperature of less than 1.5° C. Taking the latent heat of fusion as 400 J/g and the specific heat as 1.2 J/g, the amount of fusion possible is only 0.45 per cent. This is inadequate to provide magma on the scale required to explain the uplift of the ocean ridges.

The alternative mechanism is that an upwelling mantle convection current causes fusion in its upper reaches (Fig. 4). Since the fusion gradient is steeper than the adiabatic gradient, fusion is restricted to the topmost section of the rising current. As material is carried upwards in the convection current, it follows a temperature gradient slightly in excess of the adiabatic gradient (Fig. 3, AB) until it reaches the fusion boundary (or zone) until fusion (or partial fusion) is complete (Fig. 3, BC). Taking the difference between the fusion and adiabatic gradient

Fig. 3. Mechanism of partial fusion in a rising convection current. AB represents a temperature gradient slightly in excess of the adiabatic gradient. Partial fusion commences as the upwelling current passes B, and continues until C with a steeper temperature gradient. No further partial fusion occurs in the topmost section of the convection cell CDE. Cooling by thermal conduction affects DEF. A fusion zone is shown, since this is more realistic than a simple two-phase boundary.

Fig. 4. Mechanism suggested for the uplift of oceanic ridges in isostatic response to a mass deficiency caused by dilatation on partial fusion. Partial fusion occurs in an upwelling mantle convection current.

to be  $1^{\circ}\text{C}/\text{km}$  and latent and specific heats as above, the amount of fusion is 10 per cent in a 33 km rise. Here we have a powerful mechanism for producing magma on a very large scale in a rising convection current. The existence of more than one solid phase complicates the argument but does not alter the conclusion. In reality, it is likely that the olivine present cannot fuse completely, and thus that there is a limit to the degree of partial fusion possible.

The magma produced in this way would tend to rise towards the Earth's surface owing to its relatively low density. It is likely to form a network of dykes and magma chambers in the layer overlying the convection cell. In this way, the mass deficiency causing the uplift is probably partly within the topmost part of the upwelling current and partly in the overlying layer, where it may build up to a substantial fraction locally.

Subsidence of an ocean ridge would occur when the underlying low-density rocks increased in density to the normal value appropriate to their depth. On the convection hypothesis, this would start happening when the convection current died out, causing the source of fresh magma to disappear. The residual magma would partly rise towards the Earth's surface to solidify rapidly, forming lava flows and near-surface intrusions: part of the magma would probably remain trapped in the upper mantle where it would solidify more slowly by cooling through the geothermal gradient. Calculations show that magma distributed uniformly between depths of about 60 km and 200 km would probably solidify in a period of about 80 my. at the most.

The uplift and subsidence of oceanic ridges have important implications for the stratigrapher, as recognized by Hallam<sup>21</sup> and Menard<sup>22</sup>. Uplift of an oceanic ridge would cause eustatic rise in sea-level of the order of 100 m, and subsidence of a ridge would cause a regression of similar magnitude. In general, this mechanism explains transgressions and regressions of world-wide incidence. In particular, it may explain the extraordinarily widespread and deep transgression at the base of the chalk and the similar regression when the chalk seas withdrew.

### Conclusions

The low-density underlying rocks causing the uplift of the oceanic ridges and the western United States lie in

the upper mantle, and substantially result from partial fusion, although other causes such as serpentinization may contribute. The evidence leading to this conclusion comes from a combination of geological, geophysical and geochemical discoveries of recent years, and particularly the present burst of oceanographical research. When pieced together, this evidence suggests rejection of other hypotheses such as crust-mantle mix and solid-solid phase changes as the major cause on the assumption that a single mechanism is of prime importance throughout the whole system of ocean ridges. The hypothesis of partial fusion, however, seems to be consistent with all the lines of evidence.

The only mechanism known for causing magma generation on such a large scale depends on the reduction of confining pressure in an upwelling convection current in the mantle. Such convection currents appear to rise beneath the oceanic ridges, causing their volcanism and uplift.

The hypothesis is equally applicable to uplifts such as the East Pacific Rise which have taken place without associated horizontal movements, and to the Mid-Atlantic Ridge where in addition to the vertical uplift new oceanic crust may be in the process of formation.

## LETTERS TO THE EDITOR

## ASTRONOMY

## Surface Relief of Mars

THE first reports from *Mariner IV* indicate that the planet Mars possesses a negligible magnetic field when compared with that of Earth. This is strong confirmation of the view that Mars has not developed a core. In a recent communication to *Nature*<sup>1</sup> we suggested that a cyclical process which can be discerned in the Earth's history, and is responsible for its major geological structures, is related to the development of the Earth's core. If our arguments are valid, then it can be predicted that Mars will not possess any system of orogenic mountain belts comparable with those of Earth. Any relief on its surface would be of volcanic or volcano-tectonic origin as on the Moon.

## OCEANOGRAPHY

## Morphology of North Macquarie Ridge

SOUNDINGS in the Southern Ocean between New Zealand and the Antarctic continent have been sufficient to permit definition of a general elevation of the sea floor extending from the Balleny Islands region, across the Pacific Antarctic and Indian Antarctic Ridge junction, north through Macquarie Island towards New Zealand. This elevation, the Macquarie Ridge, is commonly depicted on bathymetric charts either as a substantially continuous feature at least as far north as Macquarie Island with its crest lying in depths between 1,000 and 2,000 metres; or as in the chart utilized by Adie<sup>1</sup>, with an extensive deep water gap separating the northern end of the Ridge from New Zealand.

For a number of years the N.Z. Antarctic Research programme has included studies of the Macquarie Ridge between the Antarctic continent and New Zealand carried out by the New Zealand Oceanographic Institute and Geophysics Division, Department of Scientific and Industrial Research.

The principal geological objectives have been to define the morphology of the Ridge and to elucidate its structure. The aim of zoological work has been to throw light on the biogeographic relation of the benthic fauna of the New Zealand region with that of various areas to the south and on the ridge as a faunal dispersal route.

The question whether the elevation on which Macquarie Island lies extended north to New Zealand as a major ridge has hitherto been unresolved. Hardman stated<sup>2</sup> that "On the (sounding) evidence now available it appears . . . that the existence of a connection between New Zealand and the Macquarie Rise is doubtful".

Fell<sup>3</sup>, in discussing the biogeographic relationships of the New Zealand and Antarctic echinoderm faunas, stresses the apparent differences between the Macquarie Island and New Zealand elements, and correlates these with the circumstance that "Macquarie Island . . . stands in deep water" and there is " . . . no available shallow water route between the two regions".

In discussing the hydrology Deacon<sup>4</sup> states: "The bottom topography south of New Zealand is so irregular that the eastward current (of deep water) must be interrupted by numerous eddy movements. . . . The deep channel between the New Zealand shelf which extends as far south as the Campbell and Auckland Islands, and the Antarctic shelf, is less than 1,000 miles wide and is obstructed by several shallow banks and islands. A preliminary examination of our soundings . . . suggests that the bottom topography is even more rugged than has hitherto been supposed".

In view of the significance, in the three fields of geology, zoology and hydrology, of proper resolution of the question, numbers of echo-sounding traverses have been made in a south-east-north-west direction from the Foveaux Strait region just south of New Zealand to 58° S. of Macquarie Island. These traverses have extended from the Campbell Plateau and South-western Pacific Basin west to the Tasman Basin; each of them crossing the possible location

Fig 1

of the ridge: The traverses were on the average 40 nautical miles apart.

Most of this work was carried out during N.Z. Oceanographic Institute cruises on H.M.N.Z.S. *Endeavour*, but other available soundings have been utilized to construct the accompanying bathymetric chart (Fig. 1).

The principal morphological features that became apparent in the area between Macquarie Island and New Zealand are:

(i) A general ridge form extends north from Macquarie Island to the New Zealand shelf (in the Pyusegur Point area).

(ii) Much of the ridge is shallower than 2,000 metres, little of the crest is shallower than 1,000 metres.

(iii) The maximum distance between portions of the ridge shallower than 2,000 metres is 35 miles (near 53° 30' S. and 51° S.) and here the maximum depth in these intervals is less than 4,000 metres.

(iv) Individual highs top the ridge and in places form shallow banks with flat tops now at 100 metres or less.

(v) A marked east-west offset occurs at 51° S. where the northern portion of the ridge is offset 50 miles to the east.

(vi) The foot of the western slope of the Ridge is bordered by a series of partly elongated shallow basins, analogous to the Fiordland Trough at the slope-foot of south-west South Island of New Zealand<sup>4</sup>.

(vii) A low-relief sill at just less than 4,000 metres depth separates Emerald Basin from the south-western Pacific Basin. Emerald Basin floor is a little more than 4,000 metres deep.

(viii) Solander Trough extending south from the New Zealand shelf was previously conjectured to turn west and descend to the Tasman Basin near latitude 47° 30' S. Though there is some room for ambiguity the present evidence favours an interpretation of the bathymetry in which the Solander Trough descends to Emerald Basin on the eastern side of Macquarie Ridge.

While the intervals between sounding lines still admit the prospect of further revisions of the present bathymetry, yet the possibility of a substantial deep between New Zealand and Macquarie Island is removed. The physical connexion of the ridge with the south-western corner of New Zealand rather than with any element of the Campbell Plateau calls for reorientation of both structural and biogeographic generalizations for the region and for a revision of some present views on the structure of southern New Zealand.

The spread of benthic animals with restricted larval life and specific depth requirements<sup>5</sup> can now be more readily accepted as the water gaps at given depth are shown to be reduced from those of earlier bathymetric concepts.

The present definition of the bathymetry provides a firmer basis for the detailed discussions of the geological structures of the region and of the biogeographic significance of the animals obtained that will be published elsewhere.

## GEOPHYSICS

### Sinusoidal Disturbances due to Shipping, on Seismograms at Rabaul, New Britain

UNUSUAL sinusoidal disturbances, which have been a feature of seismograms at Rabaul since continuous recording commenced in 1954, have been definitely linked with movements of shipping in the confined waters of Simpson Harbour (Fig. 1).

The disturbances, which appear to be a resonance effect, bear a marked resemblance to 'singing' events, such as are commonly noticed in offshore seismic surveys. Liu<sup>1</sup> has shown that an extended source is necessary for this phenomenon, and that it may be produced by standing waves or by multiple reflexions from a strong bottom reflector. At Rabaul, the extended source is provided by movement of a ship's propeller. It is suggested that the phenomenon, which to my knowledge has not been recognized before, should be known as 'ship-singing'.

A total of 122 disturbances has been examined, covering the periods January 1954–December 1955 and January 1960–January 1963. Of these, 59 can be correlated with the movement of overseas shipping in Simpson Harbour; in 48 cases there is no such correlation, and in 15 cases records of the movements of ships for the dates concerned are not available. Of the 48 cases for which there is no correlation, seven are known to have occurred while ships were anchored in mid-harbour, during which time they may have moved position, and five can be correlated with movement of a Diesel-powered 'workboat' which is used once weekly by Observatory staff to visit thermal areas in Blanche Bay.

Thus 71 out of 107 events have been found to correlate tolerably well with the movements of ships, while in 36 cases there is no known correlation. Since, however, movement of small inter-island ships was not recorded, it is at least possible that these remaining instances may be attributed to them. The duration of these events varied between 0.5 min and 45 min.

In 55 cases a fairly accurate estimate can be made of the position of the ship considered to have been re-

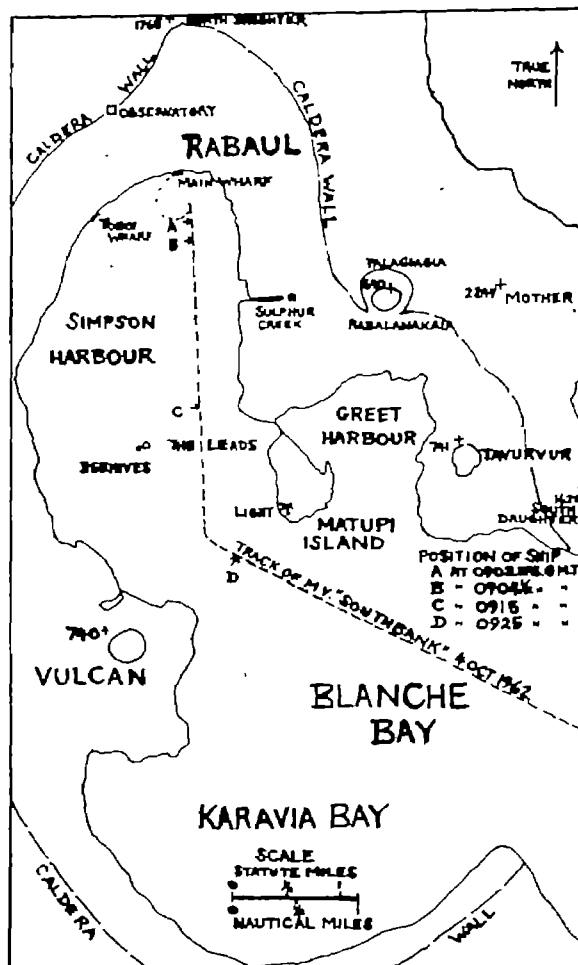

Fig. 1. Rabaul locality map

sponsible for the disturbance. In 29 of these cases ships were moving from the wharves to the 'leads' (Fig. 1), in 12 from the 'leads' to the wharves, in six from the 'leads' to the open sea, and in two from the open sea to the 'leads'. In four cases disturbances were apparently caused when the ship was moored to a wharf, usually shortly before sailing, and in two cases when ships were anchored in mid-harbour. It is evident that the phenomenon may occur at Rabaul in various positions and in various depths of water, usually 20–30 fathoms.

The size of the ship does not appear to bear a direct relationship to the amplitude of the oscillations on the seismograms. The two largest ships to have entered Simpson Harbour during the period, *Oronsey* and *Orcades* (respectively 15,122 and 15,839 registered tonnage), caused smaller sinusoidal disturbances than many which have been associated with Bank Line ships (3,000–5,000 registered tonnage). The frequency of the oscillations, which appears to be governed by the speed of revolution of the ship's propeller, varies between 0.8 and 8 c/s. Overlap of frequencies is often observed, the higher frequencies of 3–6 c/s being superimposed on lower ones which may persist for several minutes.

Fig. 2 illustrates by far the most striking example of 'ship-singing' recorded at Rabaul, in which a ground amplitude, peak to peak, of  $17\mu$  was recorded on the horizontal north-south component of the World-Wide Standardized System at the Observatory. It occurred on October 4, 1962, between 0902 and 0915 h G.M.T. (maximum at 0904.5 h G.M.T.), and is thought to have been due to M.V. *Southbank* (3,523 registered tonnage), which cast off from Main Wharf at 0850 h G.M.T. (1850 h local time).

In addition to being recorded with exceptional amplitudes on the 3-component short-period instruments of the Standardized System at the Observatory (illustrated) and on a 3-component old model Benioff seismograph at Sulphur Creek, it is the only disturbance known to have been accompanied by long-period movement. The vertical long-period component of the World-Wide Standardized System at the Observatory (also illustrated) recorded movement commencing 3 min before the short-period disturbance, at 0859 h G.M.T., and ending at 0925 h

G.M.T., 10 min after the end of the short-period disturbance at the Sulphur Creek Station. The period of this movement increased during the course of the event from 165 to 215 sec, and the peak-to-peak amplitude represented apparent ground motion of  $245\mu$ , many times greater than the maximum ground amplitude on the short-period instruments.

Movement of such a kind is unusual on the long-period vertical instrument at Rabaul. It resembles the effect due to persons in the Observatory building but is of far greater regularity. It was established that no one was in or near the building at the time, and this is confirmed by the fact that the horizontal long-period records show no trace of effects due to persons: they recorded a short-period oscillation of minute amplitude (approximately the width of the trace) such as is observed in strong motion earthquakes, but no long-period movement of any kind.

This long-period event is sufficiently unusual to suggest that it may have been connected with the exceptional disturbance on the short-period instruments, although the connexion is by no means certain. The very large apparent motion and the fact that the greater amplitudes on the short-period instruments occurred on the horizontal components suggest that the long-period disturbance may have been due to a spring-resonance effect rather than to a ground movement. It is noteworthy that it occurred well before resonance on the short-period instruments, at a time when only low-amplitude interference was being recorded.

The approximate position of M.V. *Southbank* at the time of this event was deduced from the deck and engine-room log books and is indicated in Fig. 1. The ship left the wharf at 0850 h G.M.T. and commenced to move full ahead at 0900 h G.M.T. When the maximum effect occurred the ship is estimated to have been about 2,500 yards from the Observatory, gradually picking up speed to three or four knots. 'Singing' ended on the Observatory records at 0914 h G.M.T., at which time the ship, making about eight knots, was about 5,000 yards from the Observatory. About 1 min later the event ended on the Sulphur Creek records, when the ship was approximately 2,400 yards away. Water depth along the line of origin of the disturbance is 20–30 fathoms.

Fig. 2. Three-component short-period and  $\frac{1}{2}$  long-period recordings of 'singing' caused by M.V. *Southbank* at Rabaul

When manoeuvring full ahead the propeller of M.V. *Southbank* makes about 90 r.p.m. This is in accord with the observed frequency of the disturbance, which was about 1.4 c/s.

In common with the majority of 'singing' events observed at Rabaul, most of the energy was propagated longitudinally in a north-south plane. There have, however, been occasions on which the maximum effect has been recorded on the east-west component at the Observatory, and on the north-south at Sulphur Creek.

I thank my colleagues at the Rabaul Volcanological Observatory and Mr. James Hileman of Texas Instruments, Ltd., for their help, and the Bank Line, Ltd., and the Harbourmaster, Rabaul, for information about the movements of ships.

### Ellipticity, Viscosity and Expansion of the Earth

It is known that the ellipticity<sup>1</sup> of an Earth in hydrostatic equilibrium  $(3.3532 \pm 0.0003) \times 10^{-3}$  is greater than that of the actual Earth  $(3.3535 \pm 0.0003) \times 10^{-3}$  derived from high-precision satellite observations<sup>2</sup>.

The purpose of this communication is to show that, if the gravity constant is inversely proportional to a time parameter comparable with the age of the Earth; that is, in the case of the Dirac-cosmology, then the observed ellipticity may be regarded as the ancient ellipticity of an Earth in hydrostatic equilibrium retained by its viscous inner part.

For the ellipticity, the Clairaut-equation is valid:

$$\epsilon = 3/2 J_2 + 1/2 m + 1/2 \epsilon^2 - 1/7 \epsilon m - 4/7 \lambda$$

where  $J_2 = \frac{C-A}{Ma^2}$  and  $m = \frac{\omega^2 r_1^3}{fM}$  ( $M$  is the mass of the Earth,  $A$  and  $C$  are the moments of inertia,  $\omega$  is the angular velocity,  $a$  the equatorial radius,  $r_1$  the mean radius, and  $\lambda$  a quantity of an order of magnitude of  $10^{-9}$ ).

The gravity constant,  $f$ , in the case of the Dirac-cosmology is  $f = \frac{x}{t}$ , where  $x$  is a constant and  $t$  a time parameter comparable with the age of the Earth. The recent value of  $t$  can be taken as  $4.5 \times 10^9$  years.

In the case of hydrostatic equilibrium:

$$C - A = \frac{8\pi}{3} \int_0^a \epsilon \rho r^4 dr$$

( $\epsilon$  is the ellipticity, and  $\rho$  the density, as a function of radius).

Therefore, in the case of an Earth in hydrostatic equilibrium the following expression is valid for unit time:

$$\frac{d\epsilon}{dt} = \frac{2Q}{\omega} \cdot \frac{d\omega}{dt} + \frac{Q}{t} + \left(5Q + \frac{3\rho_s}{\rho_e} - 2\right) \frac{\alpha}{a}$$

where  $Q = \frac{m}{2\epsilon} = 0.513$ ;  $\rho_s = 2.85$ , the surface density;  $\rho_e = 5.52$ , the mean density of the Earth;  $\alpha$  = the yearly radius increase.

The recent value of  $\frac{d\omega}{dt} = -4.81 \times 10^{-32}$  radian sec<sup>-2</sup> =  $-1.44 \times 10^{-14}$  rad sec<sup>-1</sup>/year (ref. 3).  $\frac{d\epsilon}{dt} = (2.9 \pm 0.3) \times 10^{-3}$ . In the case of  $t = 4.5 \times 10^9$  years the value  $\frac{d\epsilon}{dt}$  is positive only if  $\alpha > 0$ , that is, in the case of an expanding Earth.

It has been shown that the minimum rate of the Earth's expansion amounts to  $0.6 \pm 0.1$  mm/year<sup>4</sup>.

In this case the yearly value of:

$$\frac{d\epsilon}{dt} = 0.6 \times 10^{-10}$$

that is, the value of  $2.9 \times 10^{-3}$  may be obtained only in  $4.8 \times 10^7$  years.

The maximum rate of expansion gives the radius of the Earth divided by its age. This is 1.4 mm/year, and the foregoing relative change of ellipticity may occur in  $0.9 \times 10^7$  years.

If the difference between the actual ellipticity and the equilibrium ellipticity can be ascribed to viscosity, the time interval obtained can be regarded as the relaxation time of deformations retarded by viscosity. In the mantle the rigidity is always greater than  $1 \times 10^{11}$  dynes cm<sup>-2</sup>. Therefore, the viscosity (according to the Maxwell relation) is:

$$\eta = \mu\tau \geq 3 \times 10^{16} \text{ poise}$$

and probably:

$$> 7 \times 10^{16} \text{ poise}$$

It has been shown by Niskanen<sup>5</sup>, and recently by Crittenden<sup>6</sup>, that the viscosity of the subcrustal material is less than  $10^{21} - 2 \times 10^{22}$  poises, at least to a restricted depth. Therefore, the viscosity of the greater part of the mantle must exceed several times  $10^{24} - 10^{27}$  poises. This excludes the existence of convection currents in the greater part of the mantle.

### Gravity Field of the Niger Delta (West Africa)

GRAVITY data are now available for 73 land stations situated in the general area of the Niger Delta, West Africa. The Bouguer anomaly map shows a gravity low of  $-35$  mgal (the 'Niger Delta Minimum') which occupies a large part of the sub-aerial Niger Delta, and a gravity high of  $+40$  mgal (the 'Ekenie High') situated in the extreme south-western corner of the sub-aerial delta. Isostatic reduction does not very appreciably affect the anomalies, as is only to be expected in an area where the topography is low and gentle. The isostatic anomaly maps, based on various possible systems of isostatic compensation, accordingly do not differ very much one from another or from the Bouguer anomaly map, and show the same general features as the latter. However, there is some difference in the 'Ekenie High' area; isostatic anomalies there are less pronounced for a higher degree of regionality. This is interpreted as an indication that the continental slope off the Niger Delta is regionally compensated.

If the sediments constituting the Niger Delta had been laid down on a completely rigid, unyielding crust which was in isostatic equilibrium before the sediments were deposited, one would expect to find strongly positive gravity anomalies of, say,  $+125$  to  $+220$  mgal, depending on the density value assumed. In reality, gentle negative anomalies down to  $-40$  mgal are encountered. This is interpreted as meaning that the Niger Delta is practically in isostatic equilibrium. Accordingly, there must have been adjusting crustal movements (subsidence) to bring about this state of near-isostatic equilibrium and there is every reason to interpret this as subsidence under a sedimentary load.

A simple relation exists between initial water depth and the total thickness of sediment that can be deposited. If, namely,  $W$  is the initial water depth (density of sea

water is  $1.03 \text{ g/cm}^3$ ) in an area which is in isostatic equilibrium, and sediment of density  $d \text{ g/cm}^3$  is supplied until the top of the sediment reaches sea-level and the area is again in isostatic equilibrium, then the total thickness of sediment,  $X$ , is related to the other quantities by the equation:

$$1.03 W + 3.27 (X - W) = dX$$

This relation is based on the required equality of pressures at an arbitrary reference-level in the mantle, and may also be written as:

$$X = \frac{3.27 - 1.03}{3.27 - d} W \quad (1)$$

Analysis of present-day isobaths in the adjacent Gulf of Guinea indicates that the initial water depth in the area now occupied by the south-western tip of the sub-aerial Niger Delta may have been as much as 3,000 m. Accepting  $2.40 \text{ g/cm}^3$  as the most likely value for the average density of the Niger Delta sediments, the foregoing equation yields a value for  $X$  of nearly 8,000 m in conjunction with a value for  $W$  of 3,000 m. The total sediment thickness in the Niger Delta is accordingly estimated to be about 8,000 m.

A nearly identical reasoning can be applied to the case where the sea is not completely but only partially filled up with sediment. In this case, the total thickness of sediment deposited ( $X$ ) is related to the amount  $Y$  by which the sea floor has been raised after sedimentation and subsidence have again resulted in isostatic equilibrium, by the expression:

$$X = \frac{3.27 - 1.03}{3.27 - d} Y \quad (2)$$

The configuration of the sea floor before the delta was there can be inferred from the present-day isobaths by interpolation between the isobaths on either side of the delta. Everywhere,  $W$  or  $Y$ , as the case may be, can therefore be found from the difference between the inferred initial isobaths and the present-day isobaths. At all points,  $X$ , the total thickness of sediment, can hence be calculated. This simply means that the total volume of the Niger Delta can be calculated. Assuming  $d = 2.40 \text{ g/cm}^3$ , this yields a total volume of  $500,000 \text{ km}^3$  for the Niger Delta sediments.

A more detailed and complete account of this investigation will appear in the *Bulletin* of the Geological Society of America.

### Infrasonic Waves of the Auroral Zone

INFRASONIC waves of the auroral zone have been observed<sup>1,2</sup> using a suitable microphone system. These waves are thought to originate in the joule heating by the electrojet currents<sup>1</sup> or in the corpuscular heating during ionization and excitation processes<sup>3</sup> in the auroral ionosphere—at about the 100-km level. Periodic influx of electrons at this level due to processes, which may be solar, magnetospheric or extra-magnetospheric, could cause periodic fluctuations in the current systems and the heating processes; hence the observed periods (in the range 20–80 sec and, at times, upwards of 100 sec). Time-scales of this order are known in auroral pulsations. It is suggested here that it is also possible to account for the energy fluctuations from the atmospheric dynamics, specifically turbulence near 100 km, which can generate these waves via the pressure fluctuations.

It is shown elsewhere<sup>4</sup> that the time-scales of eddy decay in turbulence near 100 km can range from less than a second to several seconds going up to a few minutes; and several geophysical events show such time scales<sup>5,6</sup>.

The energy dissipation varies from approximately low values of the order  $10^{-8} \sim 10^{-6}$  to relatively high  $10^{-1} \sim 10$  erg  $\text{cm}^{-3} \text{ sec}^{-1}$ . Some of the high values are due to the high speeds used. For example, a few km/s to a few tens of km/s are known for intense and moving aurorae<sup>1-7</sup>. Scale sizes from less than 1 km to a few km can be considered. Refraining from very-high-energy rates until their implications become fully understood, still one has to consider moderately high values of the order  $10^{-4} \sim 10^{-3}$  erg  $\text{cm}^{-3} \text{ sec}^{-1}$ . During disturbed conditions, this order of energy is certainly comparable to, or in excess of, the joule heating rates. Most of the energy of this magnitude is derived either from the auroral input during strong aurorae, or from the solar input.

We can consider a 10-km thickness of the turbulent layer in accordance with the experimental results<sup>8</sup>. An estimate of the energy flux corresponding to densities of the order  $10^{-4} \sim 10^{-3}$  erg  $\text{cm}^{-3} \text{ sec}^{-1}$  would be about  $100 \text{ erg cm}^{-2} \text{ sec}^{-1}$ , or more. This is roughly the order of energy flux due to Maeda and Watanabe<sup>9</sup> required for a surface pressure amplitude of the order of 1 dyne  $\text{cm}^{-2}$ .

One can compute the pressure fluctuation magnitudes in turbulence. The order of this fluctuation will be denoted by  $\delta P$ . The only quantity having the dimension of pressure and formed from the quantities  $\delta V$  (= velocity in fluctuation),  $\rho$  (= density of the fluid), and  $l$  (= scale size of eddy), is given by  $\delta P \approx \rho(\delta V)^2$ . For the pressure and density for the height concerned, one can get fluctuations ranging from less than 1 up to 5–10 per cent. From this, during auroral periods, one could expect the order of flux required to generate the observed pressure waves.

Fig. 1 shows some of the energy sources in the ionosphere. We can assume<sup>3</sup> that the peak of the hydromagnetic heating which occurs at about 170 km is too high for the required order of energy flux to generate the pressure

Fig. 1. Relative heights of some energy sources in the ionosphere

Fig. 2. Relative variation of eddy decay time with energy dissipation rate in turbulence about 100 km

waves. The peak of the relative ionization rate is about 100 km; and auroral coruscations, micropulsations of the magnetic field and related absorption effects are attributed to this level<sup>9</sup>. Turbulent mixing becomes very little above 100 km<sup>9</sup>. Transfer processes in the momentum space is large in the region 80–100 km. Autocorrelation and power spectrum methods are certainly effective<sup>10</sup> in obtaining signal periods and the discrete frequencies that are hidden in the random noise processes. The life-time of an eddy is relatively longer as the dissipation energy decreases as shown in Fig. 2. One can certainly expect relatively longer periods for smaller energy rates.

In conclusion, turbulence near the 100-km level can be easily considered as an atmospheric source of energy modulation and, thus, for the generation of infrasonic waves.

## GEOLOGY

### Dual Classification for Point-counting Limestones

Most recent petrographic accounts of limestones utilize the classification of Folk<sup>1</sup> as a basis for quantitative description, and as a convenient shorthand for general descriptions. During studies of English Upper Jurassic limestones it has been found that point-count results using Folk's categories do not adequately convey all the characters of a particular rock specimen.

Folk divides limestone constituents into two groups: terrigenous constituents (derived from consolidated rocks outside the basin of sedimentation), and allochemical constituents (allochems) formed by physico-chemical or biological processes within the basin of sedimentation. The allochems are further divided into groups including intraclasts, oolites, pellets, and other particles of organic origin. The distinction between intraclasts and pellets is usually made by the ovoid shape of the latter, but in English Corallian (Upper Oxfordian) rocks the two particle types are of similar size and so are difficult to distinguish; therefore only one category has been used, that of intraclasts. More important in rocks of this age, however, is the admixture of allochemical and terrigenous material; thus quartz grains may form the nuclei of oolites, or possess discontinuous coats of fine-grained calcite, and hence be termed intraclasts (Fig. 1). Therefore a quantitative analysis of an oolite will include the constituent

particles, but will not detail the proportion of quartz within the sample. Similarly, the true fraction of organic carbonate material within a sample may be obscured, for, if the shell fragments are coated with fine-grained calcite, they are counted as intraclasts. Fig. 1 shows the variety of material that may constitute intraclasts or oolites.

In order to clarify the anomaly produced by point counting limestones using Folk's categories, a second count (by experience, five hundred points have been found adequate) must be made to estimate the proportion of matrix (micrite or sparite), very fine-grained allochemical material, organic and terrigenous material (not particles) present in the sample. Thus oolites possessing a quartz nucleus are registered under two categories for the purpose of the second count, as fine-grained allochemical material as well as terrigenous material.

The results obtained by the method described may readily be plotted on triangular diagrams (with end members fine-grained allochemical, terrigenous and organic; hence A:T:O) by recalculating the results to 100 per cent after subtracting the matrix total from the original result. The latter procedure is justified by the results it has produced, and also because the frequency distribution of sparite and micrite percentages (Fig. 2) is distinct in the Corallian specimens studied; however, it should be noted that the results shown in Fig. 2 are biased towards samples with micritic matrices, as extensive quantitative studies of Upper Oxfordian rocks of this

Fig. 1. Diagrammatic representation of possible compositions of intraclasts and oolites. Stippled, very fine-grained allochemical material (calcite); concentric lines, as above, but with oolite laminae; black, quartz; black and horizontal lines, fragments of organic origin.

Fig. 2. Histogram of micrite and sparite percentages in Corallian rocks; 160 specimens

Fig. 2. Triangular diagrams, with end members 100 per cent. A, very fine-grained allochemical material; T, terrigenous material; O, organic material. (a) 12 specimens from Lower and Middle Oolites, Osmington Oolite Series, coast east of Weymouth. (b) Dots, 16 specimens from Upper Oolites, locality as A; crosses, 7 specimens from Oolite Freestones (Osmington Oolite Series) of Abbotsbury and north Dorset (Marnhull). (c) 47 specimens from the 'Trigonia' clavellata beds, coast east of Weymouth.

type have been carried out. Such a division is to be expected, as micritic rocks are produced by current régimes differing considerably from those associated with primary sparry limestones.

It has often been emphasized, particularly for sedimentary rocks, that individual quantitative analyses are of little value, except when comparative evaluations of a number of results are made; it is in the latter context that the A : T : O diagrams are particularly valuable.

Fig. 3 shows the results obtained from specimens collected from the Dorset Corallian (for descriptions of which see Arkell<sup>2,3</sup>). Fig. 3a includes specimens from the Lower and Middle Oolites of the Osmington Oolite Series exposed in cliffs to the east of Weymouth; here specimens containing less than 85 per cent fine-grained allochemical material are from micritic facies marginal to lens shaped oolite banks, whereas those with such material in excess of this figure are sparry, well-sorted oolites. Fig. 3b is plotted from results obtained from the Upper Oolites; the resulting distribution is in marked contrast to Fig. 3a, showing a distinct paucity in terrigenous material, and is paralleled by the opposing dominant current direction (from the west instead of east as in the Lower and Middle Oolites), and the lack of marginal facies showing the progressive build-up of oolitic coasts around shell fragments and quartz grains. In addition, the oolites of the Upper Oolites are extremely well sorted (there being few present with diameters less than 0.7 mm), but despite this, they are set in a micritic matrix. Results obtained from the Oolite Freestones of the same age exposed at Abbotsbury to the west of Weymouth, and at Marnhull in north Dorset, are comparable to those of the Upper Oolite (crosses in Fig. 3b); these freestones are known to be in proximity to coral limestones. Figs. 3b and 3c are very similar, the latter showing results from the 'Trigonia' clavellata beds (Arkell<sup>4</sup>) to the east of Weymouth, which are of a 'lagoonal' aspect. Therefore the Upper Oolite appears to be transitional between a phase of oolite formation and calmer sedimentation, perhaps resulting in part from the erosion of earlier oolite banks nearby.

While in no way replacing Folk's excellent concept, the method described enables various 'suites' of carbonate rocks to be compared by quantitative methods. The results obtained corroborate differences observed in the field and by qualitative thin section studies, and it is hoped that the method will find useful application in carbonate rocks of other ages and localities.

I thank Dr. G. R. Orme and Prof. L. R. Moore for their advice. This work was financed by a studentship from the Department of Scientific and Industrial Research.

### Fossil Burrows on the Coast of Kenya

THIS group of several dozen burrows to be described was found in July 1963 in an outcrop on the shore situated on the east side of the entrance to Mida Creek, about 16 miles south-west of Malindi, in the Coast Region of Kenya. The reference on the Universal Transverse Mercator Grid used in Kenya is Zone 37, FG 077258.

The rock containing the burrows resembles the coquinas described by Thompson<sup>1</sup>. It is cream-coloured granular limestone which in thin section is seen to consist of fragments of shell, with some foraminifera and a few quartz grains, cemented together by calcite. In outcrop the bedding is picked out by weathering. The burrows are found in a part of the outcrop where flat-bedding overlies and truncates cross-bedding.

Thompson thought that the coquinas accumulated as off-shore bars on which dunes developed. He distinguished two sets, one at 100 ft. above sea-level, and a younger set approximately at sea-level. The outcrop containing the burrows belongs to the younger set, considered by Thompson to be of Gamblian (Upper Pleistocene) age.

The burrows were found on vertical rock faces where they have been etched out by weathering. Usually the outer half of the wall has weathered away, so that the burrow is exposed as a semi-circular groove on the rock-face, but sometimes they pass through projecting ribs of rock as circular tubes. In other cases the whole of the wall of the burrow has resisted weathering so that it stands out as a hollow cylinder. All the burrows are straight or gently curved, and vertical or steeply dipping; one was found as much as 43° from the vertical. Their diameter varies from  $\frac{1}{8}$  in. to  $1\frac{1}{4}$  in. Usually a part only of a burrow, between 6 in. and 18 in. long, was visible, but one burrow 28 in. long was exposed. Where the lower end of a burrow was visible it was a blind end with no trace of chamber or return shaft. The upper part of the burrow either ended abruptly in the upper flat-bedded part of the outcrop or was obviously weathered away. Fig. 1 shows a burrow with most of these features. The burrows were present on one outcrop only, although similar patterns of weathering and bedding were present on nearby outcrops. It seems unlikely that these structures are of inorganic origin or are casts of roots, but on modern beaches of this coast, burrows of similar diameter to the fossil ones are inhabited by the pink ghost crab, *Ocypode kuhlii*. This animal lives on sandy beaches (with sand of quartz or of calcareous debris) at about high-water mark, retreating into the surf for protection at high tide and into a shallow curved burrow at low tide. At neap tides some crabs dig very deep burrows between the high-water mark of neap tides and the high-water mark of spring tides. The deepest of these burrows which I dug out completely ended 26 in. vertically below the surface, but I followed other burrows to depths of over three feet before losing them. They ended abruptly without any trace of a living chamber. They descended less

Fig. 1. One of the fossil burrows, showing the outer wall preserved in the lower part

steeply and were more curved than the fossil burrows. However, greater differences are found between burrows of different present-day species of *Ocyrops*. Kalk<sup>1</sup> describes *Ocyrops* at Inhaca Island, Mozambique, as digging to the surface from burrows destroyed by spring tides "in wide spiral tunnels", while Milne and Milne<sup>2</sup> imply that the majority of the tunnels of the North American species *O. quadrata* are U-shaped. It seems likely, therefore, that the fossil burrows were made by some species of *Ocyrops*, perhaps burrowing deeply at neap tides. The control of burrowing by the tide might account for the occurrence of the burrows in one outcrop only. If this interpretation is correct, it supports Thompson's view of the mode of accumulation of the coquinas.

### Newly Discovered Mesosiderite containing Achondrite Fragments: the Mount Padbury Meteorite

As the result of an unusual find by the joint managers of Mount Padbury sheep station, near Meekatharra, Western Australia (latitude 25° 40' S.; longitude 118° 06' E.), a peculiar occurrence of ferruginous coated boulders has been investigated and recognized as mesosiderite material of meteoritic origin. This new find, resulting in the recovery of more than 800 lb. of material including a single 195-lb. mass, ranks only second to the recovery after an observed fall at Estherville, Iowa, in 1879, of

340 kg (750 lb.) of mesosiderite material (ref. 1, p. 119). Not more than a score of these stony irons are known (ref. 2, p. 122); they are much rarer than pallasites, and some of them are diminutive fragments or very weathered, and so are of little use for the purpose of precise petrographical investigations. This new find from Mount Padbury would be important on account of the amount of the material in itself, and the fact that, though many fragments are weathered to iron-shale, some are completely fresh and covered by only a thin iron oxide veneer. But it assumes an even greater significance with the recognition of enclaves of achondrite material up to an inch or so across and free, or nearly free, from nickel-iron, which are included within the mesosiderite matrix alongside large single crystals of olivine and lumps of solid nickel-iron. Such material must provide an opportunity to find out more about this somewhat variable group of stony-irons and even learn more concerning the wider problem of meteorite genesis.

Detailed studies now in hand will probably endorse the conclusions of Prior<sup>3</sup> and Lovering<sup>4</sup>, although the story is even more complex than those authorities suggest. Prior suggested that mesosiderites are essentially mixed meteorites of combined eucritic and pallasitic composition, the latter invading the former; but Lovering cited evidence from the Pinnaroo mesosiderite indicating that in certain cases the same two components are present but the converse is the case—the eucrite invading the pallasitic component. In the case of the Mount Padbury mesosiderite the textural evidence leaves no doubt that the relationship suggested by Prior applies, but it is even more complicated since the achondrite enclaves are highly variable and include eucrite, brecciated eucrite and diogenite, the rare hypersthene achondrite. No two thin sections of the dozen so far prepared of the abundant eucrite material are alike in texture and in many there are dissimilarities of mineralogy. The olivine did not come in with the metal but represents achondritic inclusions.

The simplest of the eucrite material shows ophitic texture and is composed of a single pigeonitic clinopyroxene, showing spectacular exsolution lamellae, plagioclase (bytownite possibly grading into labradorite and marked by conspicuous droplet inclusions, pink or dark-tinted) and a mineral of low refractive index and negative relief low birefringence giving mottled grey coloration under crossed nicols, and a biaxial positive interference figure with moderate optic angle. This last mineral is believed to be tridymite. The amount of ore mineral present is variable but it is never more than accessory. It is magnetite, not nickel-iron.

More complicated mineralogy is observed in other eucrite enclaves which show an equigranular, almost granulitic texture. The pyroxenes are in complex aggregates forming reaction rims around a central core. Several varieties of pigeonite and also hypersthene are represented in these corona assemblages.

This eucritic material recalls the Moore County eucrite<sup>5</sup>. The mineralogy and presence of droplet inclusions are comparable, but the feldspars in the Mount Padbury eucrite are well cleaved. Moore County is said to possess a fabric suggestive of crystallization in the crustal zone of an Earth-sized planet—where a similar gravitational force was operative. This new eucritic material, so varied as it is, will allow similar petrofabric studies to be carried out, to endorse this evidence or otherwise. Leaving aside this petrofabric evidence, which is difficult to reconcile with the classic theory of break-up of an asteroid-sized planet and derivation from the asteroid belt, the terrestrial appearance of this eucritic material from Mount Padbury recalls igneous rock derived from magmatic crystallization in lopoliths or other layered intrusions, and even dykes, at no great depth in the Earth's crust. This, in itself, leads one to have doubts about the possibility of asteroidal provenance (as opposed to planetary provenance). Production of such microgabbroic-

doleritic rock material even within an asteroid of the dimensions of Ceres seems difficult to envisage in the light of recent studies of basalt genesis. Moreover, beyond this anomaly there remains the anomaly of 'crustal' material trapped within denser material reasonably referred to the 'deep mantle'.

The diogenite enclaves possess granulitic texture: they are not strongly brecciated and are almost monomineralic, containing only fine specks of a more birefringent clinopyroxene, an ore mineral, apatite (?) and tridymite, of the same character as occurs within the eucrite. The presence of this tridymite and the close association of eucrite and diogenite would seem to introduce a fundamental piece of evidence to meteoritics—it suggests that calcium-rich and calcium-poor achondrites are closely related and that both probably stem from processes of magmatic crystallization.

Olivine crystals within the mesosiderite matrix are up to an inch long and have been identified (Mason, personal communication) by X-ray diffraction studies as  $Fe_{80}$ , an unusually magnesian olivine for a mesosiderite. Brecciated olivine achondrite enclaves are also present. The metallic nodules show fine-medium octahedrite etch patterns (Widmanstätten).

One of us (G. J. H. McC.) is supervising petrographic and mineralogical investigations of this new material: he thanks Dr. B. H. Mason of the American Museum of Natural History for his help, and Dr. H. B. Wiik, who is undertaking chemical analyses.

A full account of the field occurrence and external features of the meteorite is being prepared by W. H. C.

## METEOROLOGY

### Outgoing Long-wave Radiation from Indian Stations

In recent months average values have been available to us of outgoing long-wave radiation recorded by *Tiros IV* for the equatorial region between 50° E. to 110° E. and 20° N. to 20° S. These observations were obtained through the courtesy of Mr. P. Krishna Rao, of the U.S. Weather Bureau. They represent averages for 5-day periods in the pre-monsoon months of April, May and June 1962, and are shown in Fig. 1 in langley/min.

It was felt worthwhile to compare the *Tiros* observations with estimates of outgoing radiation obtained from a radiation diagram. We computed, therefore, the total outgoing radiation from the mean aerological ascent of each radiosonde station in India. The computations were made with Elsasser's radiation diagram for the pre-monsoon period, under the assumption of a cloudless sky. It was also assumed that the water-vapour content decreased linearly from 500 mbar to the tropopause. Our estimates of outgoing radiation in langley/day are given in Table 1.

In Tables 2a and 2b we have compared our estimates with the *Tiros* observations for April and May.

The very small difference, of about 10 per cent or less, between our estimates and the *Tiros* observations is of

Table 1. ESTIMATES OF OUTGOING RADIATION FROM INDIAN STATIONS (langley day<sup>-1</sup>)

Station	March	April	May
1 Varanasi	440	450	460
2 Calcutta	440	467	446
3 Jodhpur	454	481	490
4 Madras	459	458	458

6 New Delhi	440	470	463
7 Bombay	467	456	463
8 Trivandrum	434	445	432
9 Vizagapatnam	431	439	442

Table 2a. COMPARISON OF *Tiros* OBSERVATIONS WITH ESTIMATES OF OUTGOING RADIATION OBTAINED FROM A RADIATION DIAGRAM (April)

Station	<i>Tiros</i> observation (langley day <sup>-1</sup> )	Estimated value from an Elsasser diagram (langley day <sup>-1</sup> )	Difference
Trivandrum	500	445	+55
Madras	502	458	+44
Vizagapatnam	490	439	+51
Bombay	487	456	+31
Nagpur	484	458	+26
		Average	+41

Table 2b (May)

Station	<i>Tiros</i> observation	Estimated value from an Elsasser diagram (langley day <sup>-1</sup> )	Difference
Trivandrum	443	452	+10
Madras	456	458	-2
Vizagapatnam	474	442	+32
Bombay	476	463	+13
Nagpur	480	501	-21
		Average	+06

some interest. It indicates that the assumption regarding the linear decrease of water vapour content from 500 mb to the tropopause is probably correct. The generally good agreement also tends to show that the effect of dust particles in the long-wave region (4–80 $\mu$ ) is small, because this was neglected in preparing our estimates. However, it is obvious that in the short-wave region (0.5–4.0 $\mu$ ) dust particles have an important effect.

Some indication of this is obtained if we compare the results of a theoretical investigation by Das<sup>1</sup> with recent radiosonde observations by Bryson<sup>2</sup>. From an examination of the mean vertical motion during the monsoon season, Das concluded that to maintain a steady circulation, non-adiabatic cooling at the rate of 2.4° C a day was required over north-west India. But the maximum cooling, estimated from an Elsasser diagram assuming water vapour and carbon dioxide as radiators, was only 1.8° C a day. Bryson's field experiments in north-west India confirmed that the observed cooling rate was indeed 2.4° C a day as predicted by Das. His estimate of cooling by outgoing radiation was, however, 1.6° C a day, which is slightly less than Das's estimate of 1.8° C a day. It is, therefore, likely that a part of the additional cooling of about 0.8° C a day is provided by the presence of dust. In the absence of clouds, the net effect of dust particles is to diminish the amount of solar radiation received at the Earth's surface. Although this depends on the dust

Fig. 1. *Tiros IV* long-wave radiation (langley/min) averages between 50° and 110° E.

content of the air, and is difficult to estimate with much confidence, the total depletion of the direct solar beam may amount to as much as 10 per cent.

I thank Prof. R. A. Bryson, University of Wisconsin, and Dr. P. K. Das for their advice.

## PHYSICS

### Sub-resonant Response of a Mechanical System parametrically excited at its Resonant Frequency

In the course of an attempt to improve the response of an inertial seismometer to very-low-frequency frame movements, it appeared worthwhile to investigate the response of a spring-mass system subjected to parametric excitation<sup>1</sup>. The parametric excitation or 'pumping' consisted of modulating the restoring force on the mass by means of an electromechanical spring<sup>2</sup> driven from a sinusoidal current source. In the initial work the restoring force was varied at twice the resonant frequency of the system as is usually done in a degenerate parametric device. It was found both from theory<sup>3</sup> and experiment that this will increase the relative motion between mass and frame only for inputs with a frequency at or near the resonant frequency, and that the input must bear the proper phase relationship to the pump. There is no improvement for frequencies much below resonance.

Pumping at twice the resonant frequency is associated with the critical value,  $a = 1$ , in Mathieu's equation,  $\ddot{x} + (a - 2q \cos 2\alpha)x = 0$ , which governs the stability of such systems<sup>4</sup>. One would also expect to obtain gain near the other critical values,  $a = 4, 9, 16$ , etc., which correspond to pumping at the resonance frequency, two-thirds of the resonance frequency, half the resonant frequency, and so forth.

These phenomena were investigated experimentally and with a computer. Both sets of data confirmed that pumping at the resonant frequency of the system greatly increased the relative motion between mass and frame. In particular, it was found that this increase in motion can be made very large for input frequencies much lower than the resonant frequency of the device; and the increase remains constant and independent of phase relationships down to zero frequency. It is believed that this phenomenon has not been noticed before.

Table 1

	Pendulum A $T_p = 0.57$ sec	Pendulum B $T_p = 7.5$ sec
Period of input	57 sec = 100 $T_p$	6.25 min = 50 $T_p$
Motion of mass without parametric excitation	1	1
Motion of mass with parametric excitation	875	1,250

The experimental results are given in Table 1. They were obtained with two different horizontal pendulums (seismometers) with free periods,  $T_p$ , of 0.57 and 7.5 sec. These were modified to permit modulation of their period<sup>5</sup> with the spring of time-variable stiffness. Both were pumped at their free period and driven by inputs with periods many times greater than their free periods. In each case it was found that parametric excitation at the resonant frequency could produce as much as three orders of magnitude increase in the motion of the mass with respect to the frame.

An observatory-quality 'parametric seismometer' utilizing this principle is being constructed for the purpose of recording very-long-period vibrations of the Earth.

This research was supported by the Advanced Research Projects Agency and was monitored by the Air Force

Office of Scientific Research under contract AF 49(638)-1506).

### Effect of Magnetic Dilution on the Paramagnetic Behaviour of an $Ni^{++}$ Ion in the Crystal of $Ni(SO_4)_2 \cdot (NH_4)_2 \cdot 6H_2O$

It is well known that the symmetry and intensity of the electric field arising out of an axially distorted octahedral water cluster surrounding a paramagnetic ion ( $M^{++}$ ) determines its magnetic anisotropy. When paramagnetic Tutton salts are magnetically diluted by partially replacing  $M^{++}$  ions by  $Zn^{++}$  or  $Mg^{++}$  ions, the charge distribution is likely to remain the same for different concentrations of  $M^{++}$  ions in the mixed crystal. Consequently, the magnetic anisotropy per gram is expected to be almost independent of concentration in the mixed crystal.

Joglekar<sup>1</sup> did not detect any effect of magnetic dilution on the magnetic anisotropy of Tutton salts. Paramagnetic resonance investigations by Griffiths and Owen<sup>2</sup> on the magnetically dilute salt ( $Ni \cdot Zn$ )  $(NH_4)_2(SO_4)_2 \cdot 6H_2O$  showed that up to a dilution of  $Ni : Zn = 1 : 50$ , the crystal field axes and crystal field splitting at 90° K are very similar to those of the concentrated salt at 90° K. Bose *et al.*<sup>3</sup>, however, found that the crystal field about  $Ni^{++}$  ion in nickel Tutton salts is very sensitive to structure and temperature.

In order to test the foregoing points, we have measured the magnetic anisotropy of mixed crystal, of the type  $A + nB$  (where  $A$  is  $Ni(NH_4)_2(SO_4)_2 \cdot 6H_2O$ ,  $B$  is  $Zn(SO_4)_2 \cdot (NH_4)_2 \cdot 6H_2O$  or  $Mg(SO_4)_2 \cdot (NH_4)_2 \cdot 6H_2O$ , and  $n$  is the number of molecules of  $B$  associated with one molecule of  $A$  in the mixed crystal) by the well-known method of Krishnan and Banerji<sup>4</sup>. The temperature variation of the anisotropy of the crystal ( $A + 15.3 B_1$ ) was measured by following the method of Krishnan *et al.*<sup>5</sup>. The temperature was controlled by a cryostatic device due to Bose *et al.*<sup>6</sup>.

The crystal anisotropy so obtained is converted into ionic anisotropy ( $K_{\perp} - K_{\parallel}$ ), following Mookherji<sup>7</sup>. These are shown in Table 1. The temperature variation of ( $K_{\perp} - K_{\parallel}$ ) is shown in Table 2. Here,  $K_{\parallel}$  represents the ionic susceptibility along the axis of symmetry of the cluster and  $K_{\perp}$  that normal to it, expressed in c.g.s. electromagnetic units.

It is clear from Table 1 that with increase of dilution, that is, decrease of concentration of  $Ni^{++}$  ion, the anisotropy of the cluster ( $K_{\perp} - K_{\parallel}$ ) increases. This clearly demonstrates that the magnetic anisotropy is structure sensitive.

Following Mookherji<sup>7</sup>, we have calculated  $-(\alpha_{\perp} - \alpha_{\parallel})$ , the difference between the crystal field coefficients along the symmetry axis of the cluster and that normal to it from ( $K_{\perp} - K_{\parallel}$ ) values given in Table 2. It is observed

Table 1

Crystal	A	A + 3.896 B <sub>1</sub>	A + 15.14 B <sub>1</sub>	A + 15.3 B <sub>1</sub>	A + 25.22 B <sub>1</sub>
% of $Ni^{++}$ ion ( $K_{\perp} - K_{\parallel}$ ) $10^6$	100.00 186	3.24 220	0.91 243	0.89 349	0.56 355

Table 2

Temp. ° K	310	230	150	110	80
( $K_{\perp} - K_{\parallel}$ ) $10^6$	349	448	714	967	1,203
$-(\alpha_{\perp} - \alpha_{\parallel}) 10^4$	25.7	23.5	21.8	19.5	19.9

that unlike most of the concentrated nickel Tutton salts  $-(\alpha_1 - \alpha_1)$  decreases with fall of temperature, bringing out prominently the temperature sensitiveness of the field coefficients and thus supporting the findings of Boese *et al.*<sup>2</sup>

### Light Scattering by the Relativistic (Non-linear) Oscillator

A SIMPLE non-linear model of the scattering particle is the relativistic oscillator (without damping), the approximate equation of motion of which<sup>1</sup> is:

$$\ddot{x} + \omega_0^2 x - \epsilon x \dot{x}^2 = (F/m_0) \cos \omega_1 t \quad (1)$$

Here  $\epsilon = (3/2) \omega_0^2/c^2$ ,  $\omega_0$  being the linear frequency and  $m_0$  the rest mass. Assuming  $F$  of the form  $\epsilon F_0$ , a solution is  $x = A \cos \omega_1 t$ , where:

$$A = \frac{F_0/m_0}{\omega_0^2 - \omega_1^2 - \frac{\epsilon \omega_1^2}{4} A^2} \quad (1.1)$$

Setting  $F_0 = eE_0$ ,  $e$  being electric charge and  $E_0$  the field strength, the electric dipole moment  $p = ex$ , the average rate of emission  $d\bar{U}/dt = \frac{\omega^4 p^2}{30c^2}$ , and the intensity  $\bar{I} =$

$(c/8\pi)E_0^2$ , we find for the ratio of incident to emitted intensity (for  $N$  oscillators):

$$\frac{\bar{I}}{\bar{I}_0} \approx \frac{8\pi N e^4}{3m_0^2 c^4} \frac{1}{\omega_1^4 \left[ 1 - \frac{3\omega_1^2 A^2}{8c^2} \right]} \quad (2)$$

For Thomson scattering,  $\omega_0 \ll \omega_1$ :

$$\bar{I}/\bar{I}_0 \approx \frac{8\pi N e^4}{3m_0^2 c^4} \quad (2.1)$$

the cross-section remains constant as in the linear case.

For Rayleigh scattering,  $\omega_0 > \omega_1$ :

$$\bar{I}/\bar{I}_0 \approx \frac{8\pi N e^4}{3m_0^2 c^4 \omega_0^4} \cdot \frac{\omega_1^4}{\left[ 1 - \frac{3\omega_1^2 A^2}{8c^2} \right]} \quad (2.2)$$

The Rayleigh scattering cross-section decreases with the amplitude of the incident radiation of frequency  $\omega_1$ .

Using a ruby-laser beam, the Rayleigh scattering cross-section has been found<sup>2</sup> to be smaller than the classical value by a factor of  $10^3$ . With the energy flux of  $8 \times 10^{12}$  ergs/cm<sup>2</sup>/sec as a typical value, the observed reduction in cross-section is of the same order of magnitude as predicted by the formula.

**Notes added in proof.** Formulae similar to (2.2) may be derived also for the types of oscillator for which the non-linear term is proportional to  $x^3$  or to  $x^5$ . However, a numerical estimate depends on the value assumed for the factor of proportionality. Thus, the reduction in Rayleigh cross-section appears to express the amplitude-frequency relationship that characterizes any non-linear oscillator.

### METALLURGY

#### A Metastable Intermediate Phase in the System Indium-Indium Antimony

Using a technique for the ultra-fast quenching of thin metal foils from the melt by solid conduction (splat cooling)<sup>1,2</sup>, we have recently shown<sup>3</sup> that in many tin alloy systems a metastable phase of the 'HgSn<sub>1-1.5</sub>' type<sup>4</sup> ( $\gamma$ -phase, simple hexagonal, 1 atom/cell,  $a = 3.212$  Å;  $c/a = 0.9312$ ) can be obtained. This phase exists in equilibrium in the systems Sn-In, Sn-Od and Sn-Hg, and could be retained in non-equilibrium at  $-190^\circ$  C in the systems Sn + Pb, Ga, Zn, Cu, Ag, Au, Pd, Ca and Mg, at solute additions of 5-20 atom per cent, depending on the system. All these elements, in leading to the formation of  $\gamma$ , acted to reduce the valence electron concentration of tin to less than 4.0.

InSb resembles Sn in some crystal-chemical respects: identical tetrahedral bonding in  $\alpha$ -Sn (A4) and InSb (B3); existence of a metallic high-pressure modification of InSb with the  $\beta$ -Sn structure<sup>5</sup>; and identical position in the periodic table. This made it likely that a metallic phase of the  $\gamma$ -type could also be retained from a melt of InSb with a suitable addition element, if the formation of equilibrium InSb could be partly suppressed.

The eutectic system In-InSb was selected. Alloys of In + 10, 15, 20, 30 and 40 atomic per cent Sb were rapidly quenched on to Cu or Ag substrates and investigated by X-ray diffraction at  $-190^\circ$  C and  $20^\circ$  C, as described in detail in ref. 3. Especially in the alloy In<sub>75</sub>Sb<sub>25</sub>, but in lesser degree also in In<sub>65</sub>Sb<sub>35</sub> and In<sub>55</sub>Sb<sub>45</sub>, twelve additional diffraction peaks were found. These lines could be indexed with a hexagonal unit cell of the  $\gamma$ -type ( $a = 3.205 \pm 0.003$  Å;  $c = 2.981 \pm 0.006$  Å;  $c/a = 0.930 \pm 0.003$  at  $-190^\circ$  C) and correspond closely in position and intensity to the powder pattern given by Sreeraton and Ferguson<sup>6</sup> for the equilibrium  $\gamma$ -phase in In-Sn. From the relative intensities of In,  $\gamma$  and InSb lines, it was estimated that with the present cooling rates ( $10^4$ - $10^7$  °C/sec) (ref. 2) about 50 per cent of the alloy In<sub>75</sub>Sb<sub>25</sub> consisted of  $\gamma$  and that the composition of  $\gamma$  is In<sub>75</sub>Sb<sub>25</sub> with  $0.35 < x < 0.45$ . The lines observed are the only lines expected and present in the investigated  $2\theta$  range from  $20^\circ$  to  $100^\circ$  (copper K $\alpha$ ); higher angle lines are not sharp enough due to transformation and texture effects. In general, while structure determinations based on few lines are problematic, in the case of metastable alloys or high-pressure phases no other evidence is available; for the In-InSb system, the analogy of the observed diffraction lines to those of the In-Sn  $\gamma$ -phase makes the reported result certain. At room temperature, the equilibrium structure In + InSb is established. Using the  $c/a$ -ratio observed for  $\gamma$  of 0.930 and the table for valence electron concentration versus  $c/a$  values in ref. 3, a valence electron concentration of 3.80  $e/a$  is calculated for  $\gamma$ (In-InSb). This would correspond to a concentration of In<sub>65</sub>Sb<sub>35</sub> for  $\gamma$ , and would thus place  $\gamma$ (In-InSb) at approximately the same valence electron concentration as the corresponding equilibrium phase  $\gamma$ (In-Sn). The observation that a maximum amount of  $\gamma$  is obtained at In<sub>75</sub>Sb<sub>25</sub> rather than at In<sub>65</sub>Sb<sub>35</sub> can perhaps be explained on the assumption that an excess of In is necessary to prevent the formation of tetrahedrally bonded InSb nuclei on solidification, which would favour the equilibrium phases.

The formation of a second orthorhombic high-pressure phase of InSb<sup>7</sup>, in addition to the  $\beta$ -Sn type modification, with a unit cell closely related to the new  $\gamma$ -phase (distortion of the orthohexagonal basal plane of  $\gamma$  with  $b/a = \sqrt{3}$  into an orthogonal basal plane with  $b/a \neq \sqrt{3}$ ) permits the speculation that in this high-pressure phase, just as in the new  $\gamma$ -phase, the effective valence electron concentration may be less than 4.

There are also indications of the existence of a further metastable phase at the composition In<sub>35</sub>Sb<sub>65</sub> (valence

electron concentration = 4.5) in analogy with the stable phase SnSb (trigonally distorted B1); the atom sites in the new phase similarly form a rhombohedral primitive lattice. These results will be reported elsewhere.

## CHEMISTRY

### Purification of Sodium Tungstate

SODIUM tungstate is used to provide charge compensation in neodymium-doped single crystals of calcium tungstate (scheelite) which are widely used as lasers<sup>1</sup>. These crystals are generally grown by the Czochralski technique from melts which can contain up to 10 wt. per cent sodium. It is therefore desirable to remove impurities from the sodium tungstate which could lead to the formation of light-scattering centres in laser crystals incorporating this material<sup>2</sup>. In this communication, a zone-refining method of purifying the readily available reagent grade of sodium tungstate is described.

The source material was 'AnalaR' grade material which corresponds to the composition Na<sub>2</sub>WO<sub>4</sub>·2H<sub>2</sub>O. The water of crystallization was removed by heating this material in a vitreous carbon boat at a temperature of 400° C. The charge was afterwards compacted by slowly melting at a temperature of 700° C. Solidification at this stage yields a white opaque ingot. However, the passage of two molten zones, approximately 2.5 cm wide, along a 15-cm ingot produces transparent material for three-quarters of the ingot length, provided the movement rate of the zone does not exceed 1.5 cm h<sup>-1</sup>. An atmosphere of argon, flowing at a rate of 200 c.c. min<sup>-1</sup>, was used both for the compaction and for the zone-refining. Under these conditions the carbon remains chemically unattacked. The material produced in this manner is polycrystalline as expected for a substance which exhibits trimorphism<sup>3</sup>.

Samples of the transparent sodium tungstate, the impure end of an ingot and the source material have been analysed in an 'M.S. 7' mass spectrometer. The results of the analysis (Table 1) show that all the impurity elements detected, except molybdenum, have been reduced in concentration by the zone-refining process.

Table 1

Element	Concentration (p.p.m. atoms)		
	Source material	Impure end	Pure end
Mo	1,500	1,500	1,500
As	90	230	6
Ca	165	100	20
K	250	150	10
Cl	170	240	60
P	35	170	Not detected
Si	150	230	90
B	5	15	1

The reduction in the concentration of chlorine and silicon is particularly important since these elements are known to cause scatter in calcium tungstate single crystals<sup>4</sup>. The high molybdenum concentration is

unlikely to be detrimental, as sodium tungstate and sodium molybdate are isomorphous compounds which may both be used for charge compensation in scheelite structures.

We thank Mr. C. M. Wilson (A.E.I., Rugby) for his assistance with the analysis.

### Magnetic Properties of Some N : N'-bis-Salicylidene-ethylenediamine Iron (III) Complexes

THE magnetic properties of some binuclear complexes of chromium (III) and iron (III) in which magnetic interaction was considered to occur through oxygen bridging groups were reported previously<sup>1</sup>. In the cases discussed, it was not possible to fit the magnetic data very satisfactorily to a model for spin interaction between the metal ions. We report here a complex of iron (III) with N : N'-bis-salicylidene-ethylenediamine in which we have been able to establish a binuclear formulation and account for the magnetic properties satisfactorily in terms of spin interaction between the two metal ions.

The complex N : N'-bis-salicylidene-ethylenediamine iron (III)-μ-oxy-N : N'-bis-salicylidene-ethylenediamine iron (III) was first reported by Pfeiffer<sup>2</sup>. In agreement with this formulation, the complex is a non-conductor in nitrobenzene and nitro-methane and the molecular weight in chloroform and nitrobenzene corresponds to the binuclear complex (C<sub>18</sub>H<sub>14</sub>O<sub>4</sub>N<sub>2</sub>Fe)<sub>2</sub>O. The magnetic moment at 300° K was found to be 1.87 B.M., being appreciably lower than the value of 2.4 B.M. reported previously by Klemm and Raddatz<sup>3</sup> and very dependent on temperature, falling to 0.60 B.M. at 80° K. Considerable care was taken to ensure that the susceptibility was independent of field strength.

The characteristics of the magnetic behaviour may be satisfactorily accounted for using the Hamiltonian  $H = -2JS_1 \cdot S_2$ , where  $J$  is the exchange interaction between the two ions and  $S_1$ ,  $S_2$  are the spin vectors for the two ions. For  $S = 5/2$ , the susceptibility  $\chi_A$  is given by:

$$\chi_A = \frac{3K}{T} \frac{[55 + 30 \exp(10x) + 14 \exp(18x) + 5 \exp(24x) + \exp(28x)]}{[11 + 9 \exp(10x) + 7 \exp(18x) + 5 \exp(24x) + 3 \exp(28x) + \exp(30x)]} + N(\alpha)$$

where  $K = g^2 N \beta^2 / 3k$ ,  $x = -J/kT$  and  $N(\alpha)$  is a temperature-independent paramagnetic term. The figure gives the calculated curve for  $J = -100$  cm<sup>-1</sup>,  $g = 2.07$  and  $N(\alpha) = 0$ ; the values of  $g$  and  $N(\alpha)$  are of the order anticipated for an iron (III) complex with a <sup>6</sup>S ground-state. With the exception of binuclear copper (II) complexes, this is the first example of a binuclear complex with strong spin-spin interaction for which a satisfactory interpretation of the magnetic behaviour can be given.

We have also investigated the magnetic properties of the corresponding iron (III) bromide and chloride complexes over a temperature range. At room temperature the magnetic moments of the bromide and chloride are 5.41 and 5.36 B.M. respectively. These values are lower than the spin-free value of 5.92 B.M. expected for iron (III), which suggests the possibility of magnetic exchange interactions. The crystal structure of the chloride has been reported<sup>4</sup> to consist of layers of N : N'-bis-salicylidene-ethylenediamine iron (III) groups separated by 3.4 Å. However, in adjacent layers, the iron atoms are

Fig. 1. —, Theoretical results; x, experimental results

laterally displaced by about 2 Å. This structure indicates that any exchange which takes place will do so between iron atoms in chains throughout the crystal. Using this model, an approximate fit for the experimental results of the chloride and bromide has been obtained, using the parameters summarized in Table 1. However, using the binuclear model we have also obtained good fits. The parameters required are also summarized in Table 1.

Table 1

Complex	$J \text{ cm}^{-2}$	$\beta$	$N \times 10^4$	Structure assumed for curve fitting
$[\text{C}_{12}\text{H}_{14}\text{O}_2\text{N}_2\text{Fe}]_2\text{O}$	-100	2.07	0	Binuclear
$[\text{C}_{12}\text{H}_{14}\text{O}_2\text{N}_2\text{Fe}]_2\text{Cl}$	-8.0	2.06	0	Binuclear
	-7.0	2.10	0	Long linear chain
$[\text{C}_{12}\text{H}_{14}\text{O}_2\text{N}_2\text{Fe}]_2\text{Br}$	-7.5	2.06	0	Binuclear
	-7.0	2.10	0	Long linear chain

In chloroform solution, the bromide and chloride complexes are monomeric and in nitro-methane they are non-conducting. It has not been possible to determine the magnetic susceptibility of any of the complexes in solution due to their limited solubility.

### Use of Phosphoric and Sulphuric Acids in Hydrocarbon Electrode Investigations

DURING an examination of hydrocarbon electrodes, evidence was obtained which confirms that analytical reagent grade phosphoric and sulphuric acids contain an oxidizable impurity. The cell and procedures used will be described elsewhere<sup>1</sup>. In Fig. 1 is shown a plot of potential versus log apparent current density for platinized platinum immersed in nitrogen-stirred unpre-electrolysed 5M  $\text{H}_2\text{PO}_4$  at 80°C (inverted triangles). Prior to these measurements the system had not been in contact with a hydrocarbon or any other oxidizable material. The slope of the linear part of the curve is 143 mV. After an anodic pre-electrolysis (60 h at an anodic current density of 62 mA/cm<sup>2</sup>), the Tafel behaviour was no longer observed with nitrogen stirring, and a limiting current was reached (triangles, Fig. 1). When the purified acid was stirred

Fig. 1. Current-potential relations for electrodeposited platinum black in 5M  $\text{H}_2\text{PO}_4$  at 80°C. V, nitrogen, unpre-electrolysed acid;  $\Delta$ , nitrogen, anodically pre-electrolysed acid; O, ethylene, anodically pre-electrolysed acid

Fig. 2. Current-potential relations for electrodeposited platinum black in 3N  $\text{H}_2\text{SO}_4$  at 80°C. V, nitrogen, unpre-electrolysed acid;  $\Delta$ , nitrogen, anodically pre-electrolysed acid; O, ethylene, anodically pre-electrolysed acid

with ethylene at 80°C, the polarization curve obtained (circles, Fig. 1) was identical with that obtained with nitrogen stirring of the unpre-electrolysed acid. Similar data obtained with 3N  $\text{H}_2\text{SO}_4$  are shown in Fig. 2. The slope of the linear parts of the curves in this case is 183 mV.

The Tafel behaviour exhibited by the nitrogen-stirred unpre-electrolysed solutions, which is no longer observed after purification, strongly suggests the presence of an oxidizable impurity. The higher limiting current in 3N  $\text{H}_2\text{SO}_4$  than in 5M  $\text{H}_2\text{PO}_4$  after purification indicates that pre-electrolysis is not so effective in removing the impurity from the former. It is interesting to note that the impurity gives the same Tafel slope as ethylene<sup>3</sup> and other unsaturated hydrocarbons<sup>4</sup>. Another interesting feature is that the polarization curves for ethylene and propylene do not appear to be affected by the impurity. In the unpre-electrolysed solutions, however, the electrode reaction probably involves the simultaneous oxidation of the hydrocarbon and the impurity.

An unresolved problem concerning hydrocarbon electrode reactions is the mechanism responsible for the potentials observed at rest. Since the thermodynamically reversible values are not obtained<sup>3,4</sup>, it would seem that a complex process is involved. Four interpretations of these potentials have been suggested<sup>5</sup>; but none of them is entirely satisfactory. An interesting feature is that the potentials are only slightly different from those obtained with nitrogen before the ingress of hydrocarbon<sup>3,4</sup>. This observation was also made in the present work. Since a platinized platinum electrode, which is exhibiting an 'oxide' potential, can be depolarized by oxidizable sub-

stances such as methanol, formaldehyde, and formic acid<sup>6</sup>, the possibility that the oxidizable impurity contained in unpurified 5M  $H_3PO_4$  and 3N  $H_2SO_4$  plays a part in the establishment of the 'nitrogen potential' was investigated.

It was found that the 'nitrogen potential' initially at 80°C in unpre-electrolysed 5M  $H_3PO_4$  was  $\sim 1,000$  mV and in 2-4 h, the potential dropped to 300-400 mV. When the 5M  $H_3PO_4$  had been anodically pre-electrolysed as described, the potential dropped from 1,000 to  $\sim 850$  mV in approximately 2 h, and in four days it dropped to about 780 mV. After an additional seven days, it dropped to 300-600 mV. With both unpre-electrolysed and pre-electrolysed 3N  $H_2SO_4$ , the 'nitrogen potential' fell from an initial value of  $\sim 950$  to  $\sim 300$  mV in approximately 2h.

When a platinized platinum electrode that has been exposed to air is immersed in an acidic electrolyte, the high potential observed initially (1,060 mV) is probably a mixed potential, arising from the interaction of the 4-electron  $O_2/H_2O$  reaction and the Pt/Pt-O reaction<sup>7</sup>. In a nitrogen atmosphere, which would sweep out any entrained oxygen, the potential drops to about 850 mV, the potential of the Pt/Pt-O reaction<sup>7</sup>. Hoare showed<sup>8</sup>, using bright platinum in 2N  $H_2SO_4$  at 25°C, that the potential fell from about 880 to 770 mV in 25 h, and Schuldiner and Roe<sup>9</sup> showed that in a system in which rigorous steps had been taken to exclude oxygen, a potential of about 400 mV was obtained with helium stirring after several hundred hours. The steady drop in potential below 880 mV has been attributed to the instability of Pt-O in the absence of oxygen which chemically decomposes or dissolves in the platinum<sup>8,9</sup>. The lower potentials observed are considered to be dipole potentials<sup>10</sup>.

The results obtained here, particularly with phosphoric acid, suggest that the more rapid decline of the 'nitrogen potential' in the unpurified acid might be the result of the reduction of Pt-O by the impurity, as the removal of the impurity leads to a much lower rate of decline. In sulphuric acid, the potential decay was equally rapid before and after purification. This might mean that the impurity is not completely removed by anodic pre-electrolysis, or that the Pt-O is much more unstable in sulphuric acid than in phosphoric acid at the higher temperature. Some evidence for the first point is indicated by the higher limiting current in the pre-electrolysed sulphuric acid with nitrogen stirring than in the pre-electrolysed phosphoric acid.

## BIOCHEMISTRY

### Presence of Maltodextrins in Potato Phosphorylase Preparations

In the presence of excess  $\alpha$ -D-glucose-1-phosphate ( $\alpha$ -D-G-1-P) potato phosphorylase catalyses the *in vitro* synthesis of amylose-like polysaccharides by 1:4 linking of glucose residues to the non-reducing ends of maltodextrin primer molecules, either added or present as

impurities in the reactants. Maltotriose is the smallest molecule which will act as a primer for the synthesis<sup>1</sup>. The action pattern of the enzyme has been shown to be of the 'multichain' type over a wide range of conditions<sup>1</sup>.

The isolation procedure described by Baum and Gilbert<sup>2</sup>, involving specific adsorption of the enzyme on to retro-graded amylose, was used to prepare phosphorylase. Traces of hydrolytic enzymes, principally  $\alpha$ -amylase, were removed by heating the phosphorylase preparation at 53.5°-54° C for 10 min<sup>3,4</sup>; their removal was confirmed by incubating the phosphorylase with a solution of natural amylose at 20.0° C at pH 7.0. None of the phosphorylase preparations examined produced a fall in the intrinsic viscosity of the amylose over a period of 24 h. Purified phosphorylase gave a single symmetrical peak in sedimentation velocity experiments (Fig. 1) and a single line in Ouchterlony agar double diffusion experiments using rabbit anti-potato proteins antiserum. The enzyme activity of the preparations was measured in terms of the Green and Stumpf unit<sup>5</sup>. Protein concentrations were determined on concentrated samples of the enzyme either colorimetrically by Folin's method or by optical density measurements at 280 m $\mu$ . The preparation had a specific activity of about 12-13 Green and Stumpf units/mg protein.

Incubation of the enzyme with commercially available dipotassium  $\alpha$ -D-G-1-P (British Drug Houses, Ltd., Poole, Dorset) at either 20° C or 38° C at pH 7.0 resulted in the synthesis of maltosaccharides in the absence of added primer. This indicated that either the enzyme preparation or its substrate, or both, were contaminated with maltodextrins. Similar observations have been made by other workers<sup>6</sup>.

Experiments were carried out which indicated that most of the primers were present as impurities in the  $\alpha$ -D-G-1-P. However, phosphorylase was found to synthesize iodine staining maltosaccharides using chemically synthesized  $\alpha$ -D-G-1-P as the substrate; indicating that the enzyme preparation also contained primers.

The maltodextrin impurities in  $\alpha$ -D-G-1-P could be removed entirely, either by preparative paper chromatography or more simply by incubating an excess of  $\alpha$ -D-G-1-P with purified phosphorylase and growing the maltodextrins to a sufficient size to be separated from  $\alpha$ -D-G-1-P by dialysis through 'Cellophane'.

The effective primer concentration present in the enzyme preparation was determined quantitatively by comparing the rates of amylose synthesis in the presence and absence of known concentrations of chromatographically pure maltopentose under standardized conditions. The amylose synthesis was followed by removing samples

Fig. 1. Sedimentation pattern obtained from a sedimentation velocity experiment with potato phosphorylase in the Spinco model B analytical ultracentrifuge. Speed 59,780 r.p.m.; temperature 20.0° C, photograph taken 28 min after reaching set speed; phase plate angle 55°; enzyme concentration 3-4 mg/ml in 0.06 M citrate buffer, pH 7.0, containing 0.2 M NaCl.

Fig. 2. Variation in rate of amylose synthesis with change in concentration of added maltopentose. Substrate: primer-free  $\alpha$ -D-G-1-P. —○—, Synthesis on enzyme primers alone. —□—, Synthesis with 1.25  $\mu$ g/ml. maltopentose added. —●—, Synthesis with 2.5  $\mu$ g/ml. maltopentose added.

from the reaction mixtures at suitable intervals of time and staining these with iodine-potassium iodide solution under standard conditions. The extinction of the stained solution was measured in a Hilger Spekker absorptiometer at 680 m $\mu$  (No. 8 filter) and this provided a measure of the amylose synthesized. The rate of amylose synthesis was shown to be proportional to the added primer concentration (Fig. 2) and thus the primer content of the enzyme preparation could be calculated in terms of maltopentose.

At first it seemed probable that the primers in the enzyme preparation were soluble maltodextrins introduced during the preparative procedure. However, it was found that all the enzyme preparations examined had primer activity of the order of 0.45  $\mu$ g maltopentose per Green and Stumpf unit of enzyme.

Several methods were used in an attempt to remove the enzyme primers. These methods were: (a) dialysis of the enzyme to remove small, non-protein molecules; (b) incubation of the enzyme in 0.2 M phosphate buffer at 38° C at pH 6.5 to digest the primers, followed by dialysis; (c) ultracentrifugation of the preparation to sediment the enzyme, leaving smaller molecules in solution; (d) treatment of the enzyme with purified  $\beta$ -amylase to degrade maltosaccharide impurities. The first three methods had no significant effect on the primer: enzyme ratio. Husemann<sup>3</sup> has recently reported the removal of enzyme primers by dialysis; but it is probable that these primers were present initially greatly in excess of the critical ratio. It was impossible to test for primer activity in the presence of  $\beta$ -amylase and attempts to remove this enzyme resulted in complete loss of phosphorylase activity. The instability of the phosphorylase after  $\beta$ -amylase treatment may be connected with the removal of primer. Preliminary experiments, in which the enzyme was subjected to equilibrium dialysis against maltotetraose primers by passage through 'Sephadex G 100' columns saturated with carbon-14 labelled maltotetraose primers in phosphate buffer at pH 7.0, indicated that the bound primers could be exchanged for primers of known structure and size.

The constant ratio of primer concentration to enzyme activity suggested that primer was reversibly bound to the enzyme molecule in some way. Assuming an equimolar association, the ratio indicated a molecular weight of the

order of 180,000 for potato phosphorylase. This was in good agreement with values of the order of 200,000 calculated from ultracentrifuge sedimentation velocity measurements<sup>4,5,7</sup>.

These investigations were made as preliminary investigations into the *in vitro* use of potato phosphorylase for the preparation of synthetic amyloses with molecular weights of the order of 1,000,000 for use in ultracentrifugal investigations. High molecular weight amyloses have been synthesized and details of their properties will be published later.

Samples of chromatographically pure maltopentose and chemically synthesized barium  $\alpha$ -D-G-1-P were kindly supplied by Dr. S. A. Barker, Chemistry Department, University of Birmingham.

The work was supported in part by a University of Birmingham research scholarship (J. W.) and by the Agricultural Research Service, U.S. Department of Agriculture, under grant P.L. 480 (D. E. N.).

### Precipitation of Salmon Sperm Deoxyribonucleic Acid with Purine-specific Antibody

DEOXYRIBONUCLEIC acids (DNA) have been found to react with antisera prepared by immunizing animals to Gram-negative bacteria<sup>1</sup>, DNA<sup>2</sup>, nucleosides<sup>3-5</sup>, nucleotides<sup>6</sup>, purines<sup>7-9</sup> and pyrimidines<sup>10</sup>. This was first demonstrated by complement fixation<sup>1,6</sup> and then by precipitin reaction<sup>2-5</sup>. The ease and degree to which these reactions occur seem to depend on the source of the DNA. Pneumococcal and *E. coli* DNA, undenatured and denatured, fix complement with pyrimidine specific antibody; but these and calf thymus DNA are reported to require heat denaturation for complement fixation with anti-purinoyl antibody, although some complement fixation was observed with undenatured pneumococcal and *E. coli* DNA<sup>6,9</sup>. For precipitation, calf thymus DNA required heat denaturation to bring down anti-calf thymus<sup>3</sup> or anti-uridine antibody<sup>3</sup> and heat denaturation in the presence of formaldehyde to precipitate with anti-purinoyl, anti-pyrimidine or anti-nucleoside antibody<sup>4</sup>. In contrast, heat-denatured chick embryo DNA precipitated both with anti-purinoyl and anti-nucleoside antibody<sup>5</sup>. The difference in reactivity between calf thymus and chick embryo DNA was accounted for on the basis of the lack of hyperchromicity for heat-denatured chick embryo DNA and formaldehyde denatured calf thymus DNA, cycled slowly through the thermal transition temperature, compared to a hyperchromicity of 19.5 per cent for heat-denatured calf thymus DNA treated similarly<sup>4</sup>.

In the course of experiments designed to detect and isolate DNA using immuno-adsorbents, we have found that salmon sperm DNA reacts with anti-purinoyl antibody to some extent without heat denaturation and to a greater extent after heat denaturation.

Antiserum was obtained from New Zealand white rabbits immunized with 6-trichloromethylpurine coupled

to California giant keyhole limpet haemocyanin<sup>8</sup>. A stock solution of highly polymerized salmon sperm DNA (California Corporation for Biochemical Research, Los Angeles) containing 1.00 mg DNA/ml. in 1 per cent saline was prepared. A portion of this was denatured by heating at 100° C for 15 min followed by rapid chilling of the solution in an ice bath. Quantitative precipitin reactions were carried out as described by Kabat and Mayer<sup>10</sup>. Protein was determined by the method of Lowry<sup>11</sup>, using rabbit  $\gamma$ -globulin as a standard.

Quantitative precipitin curves for the reaction of heat-denatured salmon sperm DNA with the purine-specific antiserum showed an equivalence zone elongated in the region of antigen excess (Fig. 1). In control experiments using DNA and normal rabbit serum non-specific precipitation was small. The antiserum was found to contain 590  $\mu$ g of anti-purinoyl antibody per ml., by precipitation with 6-trichloromethylpurine conjugated to bovine serum albumin<sup>9</sup>. Of this antibody, approximately 32 per cent precipitated with the thermally denatured salmon sperm DNA. Typical quantitative precipitin reactions were also observed with the unheated salmon sperm DNA; however, the antigen-antibody weight ratios varied somewhat (Fig. 2). Up to 17 per cent of the antibody precipitated with the untreated DNA, about half that for the heat-denatured material.

A sample of DNA from *Olostridium* sp. (Worthington Biochemical Corporation, Freehold, New Jersey) was thermally denatured and tested with similar results. Approximately 33 per cent of the anti-purinoyl antibody precipitated at equivalence.

The denatured salmon sperm DNA shows little hyperchromicity on heating above the thermal transition temperature, followed by slow cooling, and thus resembles the

Fig. 2. Quantitative precipitin reaction curves for antiserum with unheated salmon sperm DNA

chick embryo DNA and formaldehyde denatured calf thymus DNA in thermal behaviour. It is interesting to note that Christian, DeSimone and Abruzzo<sup>1</sup> found that complement fixation for undenatured salmon sperm DNA was 22 per cent of that for the denatured DNA.

The reactivity of DNA with antibody thus seems to be dependent on the ease, degree and irreversibility of DNA denaturation. Particularly for the case of antibody to purine derivatives, the results are consistent with the DNA model wherein the bases are hydrogen bonded within the double helix and so are relatively inaccessible to antibody except at the ends or non-helical portions of the molecule. It would appear that our results are in accord with the suggestions of Butler *et al.*<sup>6</sup> that the extent of reaction to DNA with antibody to purines and pyrimidines or their derivatives may be used as a measure of the 'nativeness' of DNA.

Our observation that the incomplete precipitin reactions of salmon sperm DNA with anti-purinoyl antibody display an equivalence zone is somewhat at variance with a suggestion that DNA might react completely with this antibody if sufficient antigen were present<sup>8</sup>. The sources and treatment of the DNA, however, were different for each case. Precipitation of anti-purinoyl antibody with thermally denatured salmon sperm and *Olostridium* DNA has the characteristics of a cross-reaction between antibody and a heterologous antigen. If all the anti-purinoyl antibody could react with the DNA or even some specific fraction of the DNA, then by continued addition of antigen all the antibody would eventually be precipitated. This is not the case. As with anti-5-acetyluracil antibody<sup>8</sup>, only a portion of the antibody precipitates with the DNA. By interfacial ring test, anti-purinoyl antibody could be detected in the supernatant fluid at equivalence. Precipitation of all anti-adenosine, anti-ribosylthymine<sup>8</sup> and anti-uridine<sup>8</sup> antibodies, on the other hand, indicates that antibody to DNA components and their derivatives may react completely with DNA.

We have found that our samples of salmon sperm and *Olostridium* DNA, thermally denatured in the absence of formaldehyde, precipitated with anti-purinoyl antibody and showed only slight hyperchromicity after re-heating past the thermal transition temperature and cooling slowly, thus resembling formaldehyde denatured calf

Fig. 1. A, Quantitative precipitin reaction curve for antiserum with thermally denatured salmon sperm DNA, B, quantitative precipitin reaction curve for normal rabbit serum with thermally denatured (x) and unheated (O) salmon sperm DNA (control)

thymus and chick embryo DNA<sup>8</sup> in their immunochemical reactions. Comparison of the reported base composition of salmon sperm DNA<sup>12</sup> with those of calf thymus and chick embryo DNA<sup>8</sup> disclosed little difference.

### Serum Cholesterol Concentrations in Chicks

We were very interested in the article by De Somer *et al.*<sup>1</sup>. Their results are in good agreement with our earlier observation, where the influence of several antibiotics on the stability of fat emulsions was studied<sup>2,3</sup>. The emulsion was prepared by using a mixture of 3.0 ml. olive oil, 1.5 ml. 0.9 per cent NaCl and 1.5 ml. human duodenal juice; after 2 h of shaking the percentage of split ester bonds was estimated and the stability of emulsion was observed during the following 60 min. The addition of neomycin sulphate in concentrations (1 mg/ml., 10 mg/ml., 100 mg/ml.) corresponding to a dilution of a therapeutic dose in 10,000 and 1,000 ml. of digestive juice caused a significant decrease of lipolysis and prevented the formation of a stable emulsion. A similar effect was observed with some other antibiotics. In further experiments we observed that the addition of 30 mg neomycin sulphate to 1 ml. olive oil, administered intragastrically to rats, caused a decrease of alimentary lipaemia in the next 3 h (ref. 4).

The explanation presented by De Somer *et al.* seems very probable to us. The malabsorption syndrome following the administration of neomycin, however, cannot, in our opinion, be elucidated only by the effect of the antibiotic on the precipitation of bile acids and emulsification of fat; damage to the intestinal mucosa<sup>5</sup> and the deleterious effect on the intestinal flora should also be considered. The question arises, what will be the effect of neomycin and its derivatives on lipolysis, especially in other than biphasic systems?

A. KRONDL

Institute of Human Nutrition,  
Budějovická 800, Prague 4.

<sup>1</sup> De Somer, P., Vanderhaeghe, H., and Eysen, H., *Nature*, **204**, 1306 (1964).

<sup>2</sup> Krondl, A., Vavřínková, H., Placer, Z., and Šlabochová, Z., *Proc. Symp. Antibiotics*, Prague (1959).

<sup>3</sup> Krondl, A., Vavřínková, H., Mihalác, O., and Placer, Z., *De S. Verdau u Stoffwechs. Krenk.*, **19**, 253 (1959).

<sup>4</sup> Krondl, A., *et al.*, *Amer. J. Physiol.*, **208**, 437 (1962).

<sup>5</sup> Jacobson, *et al.*, *J. Lab. Clin. Med.*, **55**, 245 (1960).

We agree with Dr. Krondl that the malabsorption syndrome following the administration of neomycin cannot be explained by precipitation of bile acids in the gut, and that disturbances in the intestinal flora, toxic effects on the mucosa and inhibition of lipase activity may play a part.

Our studies, however, were not performed in order to find an explanation for the malabsorption syndrome during neomycin therapy. The *N*-methylated derivative of neomycin described by us has lost its antibiotic properties and does not cause a malabsorption syndrome in patients taking the drug for more than 12 months at a dosage of 6 g a day. Nevertheless the compound is still an active hypocholesterolaemic agent and this effect seems to be due to an action on bile acid micelles in the gut.

We also tested the influence of neomycin, *N*-methylated neomycin and streptomycin on porcine pancreatic lipase with  $\beta$ -naphthyl stearate as a substrate in the presence of taurodeoxycholate above the critical micellar concentration (De Laey, unpublished results). In complete agreement with the studies of Krondl *et al.* we find a significant (22–48 per cent) inhibition of the lipolytic activity after addition of neomycin or *N*-methylated neomycin to the test system. However, this inhibition of lipase activity seems also to be due to an effect on the bile acid micelles because no inhibition of the residual lipolytic activity was observed when bile acids were omitted from the test system or when taurodeoxycholate was present at submicellar concentrations (0.05–0.8 mM). Furthermore, streptomycin, having only mild bile acid precipitating activity, was also significantly less active in inhibiting porcine lipase activity.

### Hexosamine in *Bombyx mori* Silk

CONSTITUENTS other than protein in *Bombyx mori* silk have received little attention<sup>1</sup>. The significant amounts of hexosamine found in hair and wool<sup>2</sup> prompted this study to quantitate and to identify the amino-sugars in *B. mori* silk.

Raw silk was obtained from Gerli and Co., Inc., Park Ave., New York, and ground in a Wiley mill. For dry weight determinations, aliquots were dried in a vacuum drying apparatus over boiling toluene with P<sub>2</sub>O<sub>5</sub> as a desiccant. The ground silk was hydrolysed with twenty times its weight of 4 N HCl in sealed tubes overnight at 104° C. The hydrolysates were dried and purified on Dowex 50 × 8 cation exchange resin using 1 × 5 cm columns after the method of Boas<sup>3</sup> and 1 × 45 cm columns after the method of Gardell<sup>4</sup>. Hexosamine was quantitated with the Elson-Morgan reaction<sup>5</sup> using glucosamine standards. The amino-sugars were identified by chromatography of the ninhydrin degradation products from peaks derived from the long columns<sup>6</sup>.

Two Elson-Morgan reactive peaks were obtained from the Gardell columns and these were degraded with ninhydrin to arabinose and lyxose respectively. The total amounts of hexosamine derived from both the Boas and Gardell methods agreed quite well, 1.52 and 1.47  $\mu$ M/100 mg dry weight silk respectively of which slightly more than half (56 per cent—see Table 1) was glucosamine.

*B. mori* silk has significant quantities of the hexosamines, glucosamine and galactosamine present in nearly equivalent amounts.

Table 1. HEXOSAMINE IN *B. mori* SILK

Boas method Total	$\mu$ M/100 mg dry weight		Total
	Glucosamine	Galactosamine	
1.52	0.82	0.66	1.47

### Solubility of Renal Stones

THE cause of renal stone formation is unknown. Of the many current theories, majority opinion probably favours a 'supersaturation' mechanism, in which the urine concentrations of the ions of a poorly soluble salt exceed the 'precipitation product' for that particular salt, thereby causing spontaneous nucleation and subsequent growth of salt crystals.

The chemical composition of most stones is complex, and even if one considers only the calcium phosphates found therein, it is not clear which particular stoichiometry is actually involved in the nucleation and crystallization processes leading to stone formation and growth. Although the presence of  $\text{Ca}(\text{H}_2\text{PO}_4)_2 \cdot \text{H}_2\text{O}$  (ref. 1),  $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$  (ref. 2) and  $\text{Ca}_3(\text{HPO}_4)_2(\text{PO}_4)_4$  (ref. 3) has been claimed from the use of X-ray crystallographic techniques, and the presence of apatites and other more basic calcium phosphates suspected, we feel that identification of these compounds in renal stones may not be relevant to the actual physicochemical relationship which exists between the ions of calcium and inorganic phosphate in the stone and their concentrations in the corresponding urine. The critical feature of 'solubility' investigations is the identification of the lattice structure of the crystal surface, since it is the surface stoichiometry which determines the solubility of the solid phase in a bathing fluid, and consequently whether a stone will dissolve or grow under a given set of conditions.

Recently, MacGregor and Brown<sup>4</sup> have applied a non-prejudicial method of determining the stoichiometry of a solubility equilibrium to bone mineral, and the same technique has now been applied to renal stones.

An unselected series of renal stones obtained from a urological clinic were finely ground and equilibrated in 'Cellophane' dialysis tubing with buffers, at constant ion strength, over the pH range 7-8. The details of the equilibration technique have been published elsewhere<sup>5</sup>.

The pH and calcium and inorganic phosphate ion concentrations were determined at equilibrium, and the negative logarithm of the ion products  $[\text{Ca}^{++}][\text{OH}^-]^2$  and  $[\text{H}^+]^2[\text{PO}_4^{--}]$  calculated. The fit of  $\text{pCa}(\text{OH})_2$  ( $y$ ) against  $\text{pH}_2\text{PO}_4$  ( $x$ ) was determined by linear regression analysis, where the regression coefficient is the negative reciprocal of the Ca : P ratio of the solubility equilibrium.

The equilibration investigations with renal stones yielded a regression coefficient of  $-0.7591$  ( $S.E. \pm 0.0201$ ) which represents a Ca : P ratio of 7.90/6. The confidence limits of this ratio, using the 's'-distribution, are 7.44/6-8.42/6 (5 per cent) and 7.25/6-8.66/6 (1 per cent).

We therefore believe that these data indicate that the solid phase determining the 'solubility' of calcium phosphate stones is octo-calcium phosphate (OCP), even although it may only be present as a surface structure

and may indeed only be a small proportion of the total mineral present.

### Stimulation of the Uptake of Water and Ions by Indolyl-3-acetic acid : Its Dependence on Nucleic Acid and Protein Synthesis

THE plant growth hormone indolyl-3-acetic acid (IAA) affects almost all aspects of growth and development, and the very remarkable promotion of growth is associated with a simultaneous stimulation of water uptake, ion uptake and several metabolic processes. We have previously presented evidence to show that the plant growth substances, IAA, gibberellic acid and kinetin, all regulate the synthesis and release of nuclear RNA and that the fraction of RNA involved has a base composition complementary to that of DNA<sup>1-4</sup>. The synthesis of nuclear protein, as well as some enzyme systems concerned with the metabolic pathways known to be affected by IAA, is also stimulated by growth promotive concentrations of IAA<sup>4,5</sup>. In this communication we report that the IAA-induced stimulation of water uptake and ion uptake also involves a nucleic acid system, that this process is inhibited by actinomycin D and that the inhibition is removed by IAA.

The materials used were disks of potato tuber 5 mm in diameter and the epidermal cells of the lower surface of the leaves of *Rhoeo discolor*, which are rich in anthocyanin and thus easy to observe under the high-power lens of a light microscope. These tissues have been used successfully by several workers in previous investigations on the effects of IAA on water uptake<sup>6</sup>. Potato disks were treated with actinomycin D, chloramphenicol, puromycin and porphyromycin 2 h after they were removed from the tuber. After a suitable incubation period IAA was added depending on experimental requirements. Thin peels of the midrib regions of *Rhoeo* were first plasmolysed in 0.5 M mannitol and deplasmolysed in water or in appropriate concentrations of the antibiotic to facilitate their uptake. This was followed by re-plasmolysis in mannitol before they were placed in IAA solution of varying concentrations. The concentrations of actinomycin D, porphyromycin, chloramphenicol and puromycin were 100  $\mu\text{g}/\text{ml}$ , 10  $\mu\text{g}/\text{ml}$ , 3.2 mg/ml, and 100  $\mu\text{g}/\text{ml}$ . Water uptake by the potato disks was determined by weighing them 22 h after incubation. Water uptake by *Rhoeo* cells was measured by noting the time taken for the cells to deplasmolyse. <sup>32</sup>P uptake was estimated by measuring the radioactivity of the dried tissue in an end-window  $\beta$ -counter. Actinomycin D, porphyromycin and puromycin were obtained through the courtesy of Dr. V. Bryson, of Rutgers University, Dr. G. Savage, of the Upjohn Co., Kalamazoo, Mich., U.S.A., and Dr. Fritz Lipmann, of the Rockefeller Institute, New York. Orthophosphate-<sup>32</sup>P was supplied by the Atomic Energy Establishment, Trombay, India.

Experiments concerning the effect of IAA on water uptake by potato disks yield a two-phase concentration curve characteristic of the effects of IAA on growth; low concentrations are promotive but higher concentrations are inhibitory. With  $10^{-4}$  M IAA water uptake is practically trebled, but when actinomycin D is also included in the incubation mixture the IAA-induced stimulation is cut down by about 50 per cent. Higher concentrations

of IAA further remove the inhibitory effect of actinomycin D and the curve continues to rise (Fig. 1). Similar results were obtained with the epidermal cells of *Rhoso*, where IAA effects on water uptake are discernible within a few minutes of application (Fig. 2).

Actinomycin D also inhibits the uptake of orthophosphate- $^{32}\text{P}$  by potato disks and here also the inhibition can

Fig. 1. Effect of actinomycin D on IAA-induced water uptake by potato disks. Potato disks treated with actinomycin D for 1 h followed by the addition of IAA. Incubation was for 22 h in darkness at 25° C

Fig. 2. Effect of actinomycin D and porphyromycin on IAA-induced water uptake by plasmolysed *Rhoso* cells. (*Rhoso* cells were treated with actinomycin or porphyromycin for 45 min, then solid mannitol was added to provide a concentration of 0.5 M. The plasmolysed cells were transferred to IAA solutions and the time taken for deplasmolysis noted)

Fig. 3. Effect of actinomycin D on  $^{32}\text{P}$  uptake by potato disks. Potato disks were treated with actinomycin D in phosphate buffer of pH 6.0 for 1 h followed by the addition of  $3.5 \times 10^4$  c.p.m./ml. orthophosphate- $^{32}\text{P}$  and IAA. Incubation was for 3 h in darkness at 25° C

Table 1. EFFECT OF IAA AND CHLORAMPHENICOL ON WATER UPTAKE BY POTATO DISKS AND *Rhoso* EPIDERMAL CELLS

Treatment	Potato disks % Water uptake	<i>Rhoso</i> Reciprocal of time taken (min) for deplasmolysis
Control	100	0.38
IAA $10^{-4}$ M	152	0.52
IAA $10^{-3}$ M	100	0.43
Chloramphenicol $10^{-4}$ M	51	0.25
Chloramphenicol $10^{-4}$ M + IAA $10^{-4}$ M	97	0.34
Chloramphenicol $10^{-4}$ M + IAA $10^{-3}$ M	93	0.30

be considerably lessened by increasing concentrations of IAA (Fig. 3).

The IAA-induced stimulation of water and ion uptake thus seems to be related to DNA-dependent RNA synthesis. Porphyromycin, which inhibits nucleic acid synthesis through its effect on purine metabolism<sup>7</sup>, retards the stimulation of water uptake by IAA, but the inhibitory effect is not reversed by higher concentrations of IAA (Fig. 2). Chloramphenicol, which inhibits protein synthesis, also inhibits IAA-induced water uptake by potato disks and epidermal cells of *Rhoso*, but here also the inhibitory effect of chloramphenicol cannot be removed by IAA (Table 1). Similar results have been obtained with another inhibitor of protein synthesis, puromycin, for both water and ion uptake. The dimethylphenol inhibition of nucleotide synthesis as indicated by phosphate esterification is only partially countered by IAA, and the inhibitory effect is never completely reversed<sup>8</sup>. It has been suggested that actinomycin D binds with guanine of DNA<sup>9</sup>.

Noodén and Thimann<sup>10</sup> have reported recently that actinomycin D at a concentration of  $10^{-6}$  M brings about a 50 per cent inhibition of IAA-induced growth. We have also evidence to show that the actinomycin D inhibition of the synthesis of nuclear RNA and protein is removed by higher concentrations of IAA. The inhibition of water and ion uptake by actinomycin D is presumably due to the inhibition of the synthesis of the enzyme system and carriers required for these processes, which in turn is regulated by specific RNAs produced on a DNA template. The evidence presented here lends further support to the contention<sup>11,12</sup> that plant growth substance action is concerned, in a large measure at least, with the regulation of RNA and protein synthesis. It is of considerable interest to mention in this connexion that, as in the case of plant hormones, the steroid hormones also stimulate the synthesis of *m*-RNA, some specific proteins and ion uptake<sup>11,12</sup>.

### Influence of Alterations in Intracellular Levels of Amino-acids on Protein-synthesizing Activity of Isolated Ribosomes

EVIDENCE has been presented which strongly suggests that the rate of protein synthesis *in vivo*<sup>1,2</sup> and *in vitro*<sup>3,4</sup> may be very dependent on intracellular concentrations of amino-acids. Of particular significance to the present

investigations was the finding that protein turn-over in surviving liver tissue was stimulated in the presence of elevated levels of a single essential amino-acid<sup>1,4</sup>. The catabolic as well as the anabolic phase of protein turn-over appeared to be augmented in these circumstances. Interpretation of the results obtained was partially obscured by the fact that intracellular compartmentation of amino-acids may exist, with the result that exogenous and endogenous amino-acids are differentially metabolized<sup>5,6</sup>. The experiments recorded here were performed in an attempt to provide definitive data on the influence of cellular levels of amino-acids on the activity of protein-synthesizing systems. The results revealed that the amino-acid incorporating activity of ribosomes isolated from liver slices incubated with a single essential amino-acid varied with the concentration of that amino-acid.

Hepatic tissue was obtained from adult male rats (160–180 g) of an inbred Sprague-Dawley strain. The animals were killed by bleeding under light 'Nembutal' (sodium pentobarbital) anaesthesia<sup>7</sup>. Liver slices were incubated in Krebs-Ringer bicarbonate buffer containing varying amounts of a single essential amino-acid. Incubation was carried out for 15 min at 37° in a Dubnoff metabolic shaker under a gas phase of 95 per cent oxygen–5 per cent carbon dioxide. After incubation, tissue and medium were separated by filtration through fine gauze. The tissue was washed once with cold *tris*-buffer solution composed of 0.25 M sucrose, 5 mM MgCl<sub>2</sub>, 80 mM KCl, and 50 mM *tris*-hydrochloride buffer, pH 7.4 (medium A).

Ribosomes were isolated from liver tissue by a modification of the methods described by Zomzely, Roberts and Rapaport<sup>8</sup>, and by Kerner<sup>9</sup>. All procedures were carried out at 0°–4°. Incubated slices or freshly minced samples of liver were homogenized in medium A (3 ml./g tissue). The homogenates were centrifuged at 10,000*g* for 10 min and the pellet discarded. The supernatant was treated with one-ninth its volume of 10 per cent sodium deoxycholate in 50 mM *tris*-hydrochloride buffer, pH 8.2, and centrifuged at 105,000*g* for 2 h. The pellet was then rinsed 3 times, re-suspended by gentle homogenization in medium A, and re-centrifuged at 105,000*g* for 1.5 h. Finally, the pellet was again rinsed 3 times with medium A and stored overnight under medium A at –60°. Amino-acid incorporating activity of 'control' ribosomes from non-incubated liver tissue was not diminished even after several weeks of storage.

Preparations of pH 5 enzymes<sup>10</sup> were obtained from the incubated liver slices and media independently, and from freshly minced liver. Tissues were homogenized in medium A. These homogenates and the incubation media were centrifuged at 10,000*g* for 10 min and the pellets were discarded. The supernatants were re-centrifuged at 105,000*g* for 2 h. The resulting supernatants were then acidified to pH 5.0 with 1 N acetic acid and centrifuged at 15,000*g* for 10 min. The precipitates were suspended in *tris*-buffer medium containing 0.25 M sucrose, 4 mM MgCl<sub>2</sub>, 25 mM KCl and 50 mM *tris*-hydrochloride buffer, pH 7.4. Finally, centrifugation of these suspensions at 300*g* for 10 min yielded supernatant fractions containing the pH 5 enzymes. These solutions were stored overnight at –60°. Activity of 'control' pH 5 enzymes from non-incubated liver tissue was unaffected by storage for several weeks.

Ribosomes and pH 5 enzymes were assayed for activity in amino-acid incorporating systems containing 0.5–1.0 mg of ribosomal protein, an equal amount of pH 5 enzyme protein<sup>8</sup>, 0.5  $\mu$ Ci uniformly labelled L-(<sup>14</sup>C)-amino-acid, 5 mM ATP, and 0.25 mM GTP in 1 ml. of medium A. After incubation for 30 min in air at 37°, the reaction was stopped by adding cold medium A containing 0.1 per cent non-labelled amino-acid. Ribosomes were recovered from the incubation mixture by centrifugation at 105,000*g* for 1.5 h. The pellet was homogenized in medium A

and treated with trichloroacetic acid (final concentration = 5 per cent). The precipitated protein was purified of free amino-acids, RNA, and lipid<sup>4</sup>, then homogenized in 70 per cent ethanol. Aliquots of this suspension were removed for determination of protein<sup>11</sup> and radioactivity<sup>12</sup>.

Prior incubation of liver slices in the presence of varying amounts of one essential amino-acid resulted in marked alterations in the amino-acid incorporating activity of ribosomes afterwards isolated from these tissues (Table 1). Thus, when the initial extracellular concentration of phenylalanine was increased from 0 to 73  $\mu$ M, incorporation of L-(<sup>14</sup>C)-leucine into protein of isolated ribosomes was elevated approximately 40 per cent. In another experiment (not shown) a further increase was noted at the highest level of phenylalanine (155  $\mu$ M). Similarly, incorporation of L-(<sup>14</sup>C)-leucine or L-(<sup>14</sup>C)-phenylalanine into ribosomal protein was enhanced when the initial extracellular concentration of threonine during prior incubation of liver slices was raised from 0 to normal plasma (228  $\mu$ M) or liver (500  $\mu$ M) levels.

Activity of the pH 5 enzymes remaining in the tissue was also altered by prior incubation of hepatic slices in media containing different concentrations of a single essential amino-acid (Table 2). Thus, incorporation of L-(<sup>14</sup>C)-leucine into protein of 'control' ribosomes was markedly increased when the pH 5 enzymes were recovered from liver slices incubated with added phenylalanine as compared with incubations in the absence of this amino-acid. Similarly, prior incubation of liver tissue in the presence of elevated levels of threonine yielded pH 5 enzymes with increased activity. No differences in activity were observed for pH 5 enzymes recovered from the medium. However, total recovery of pH 5 enzyme protein (medium plus tissue) appeared to be significantly increased when incubation was carried out in the presence of an essential amino-acid.

These and related<sup>1–4</sup> observations reveal that protein synthesis in mammalian cells is acutely responsive to variations in intracellular levels of amino-acids induced by primary alterations in the extracellular concentration of a single essential amino-acid. Thus, within 15 min after exposure of hepatic cells *in vitro* to elevated levels of one amino-acid, ribosomes and pH 5 enzyme preparations isolated from these cells exhibited increased activity in protein synthesis. The precise mechanisms underlying

Table 1. EFFECT OF INITIAL EXTRACELLULAR LEVEL OF ONE ESSENTIAL AMINO-ACID ON PROTEIN-SYNTHESIZING ACTIVITY OF LIVER RIBOSOMES

Incubation conditions for liver slices		Incubation conditions for amino-acid incorporation		Incorporation	
Amino-acid	Concentration ( $\mu$ M)	Amino-acid	Concentration ( $\mu$ M)	a.p.m./mg protein	% increase
Phe	0	Leu	100	403 $\pm$ 10	—
	73	Leu	100	575 $\pm$ 23	43
	155	Leu	100	569 $\pm$ 24	41
Thr	0	Leu	100	537; 533	—
	228	Leu	100	758; 734	37
	500	Leu	100	741; 697	32
Thr	0	Phe	25	448; 464	—
	228	Phe	25	778; 731	64
	500	Phe	25	811; 978	85

Liver slices were incubated for 15 min in the presence of varying amounts of one essential amino-acid. Normal plasma and liver concentrations for phenylalanine (Phe) were 50  $\mu$ M and 86  $\mu$ M, respectively, and for threonine (Thr) were 228  $\mu$ M and 500  $\mu$ M (ref. 4). Ribosomes recovered from the liver slices were incubated for 30 min with 'control' pH 5 enzymes and 0.5  $\mu$ Ci of uniformly labelled L-(<sup>14</sup>C)-leucine or L-(<sup>14</sup>C)-phenylalanine. Incorporation data represent individual values or averages  $\pm$  S.E.M. for three samples.

Table 2. EFFECT OF INITIAL EXTRACELLULAR LEVEL OF ONE ESSENTIAL AMINO-ACID ON ACTIVITY OF LIVER pH 5 ENZYMES IN PROTEIN SYNTHESIS

Incubation conditions for liver slices		Incubation conditions for amino-acid incorporation		Relative incorporation (%)
Amino-acid	Concentration ( $\mu$ M)	Amino-acid	Concentration ( $\mu$ M)	
Phe	0	Leu	100	100
	73	Leu	100	140
	155	Leu	100	171
Thr	0	Phe	25	100
	228	Phe	25	132
	500	Phe	25	123

Conditions were similar to those in Table 1, except that pH 5 enzymes recovered from the incubated liver slices were assayed with 'control' ribosomes. Results shown are averages calculated from three experiments with each amino-acid; 'P' values for differences at highest and lowest extracellular levels of each amino-acid were between 0.01 and 0.03.

these responses are unknown. However, in the context of presently accepted theories of the regulation of protein synthesis<sup>12</sup>, variations in the production and release of messenger RNA in response to alterations in amino-acid levels may be involved. The findings recorded here provide support for the hypothesis that primary alterations in amino-acid transport into the cell, such as those which may occur under hormonal or other metabolic influences, may be responsible for subsequent changes in protein synthesis.

## Occurrence of Esterified Hydroxy Fatty Acids as Precursors of Lactones in Butter

It has been demonstrated by Boldingh and Taylor<sup>1</sup> that butterfat contains various  $\gamma$ - and  $\delta$ -lactones in amounts of 1-20 p.p.m. Using the isotope dilution method, 5-octanolide, 5-decanolide, 5-dodecanolide and 5-tetradecanolide could be determined quantitatively.

In addition, it was found that the free lactone content rises two- to three-fold when the butterfat is heated at about 140° C. This led us to believe that butterfat contains small amounts of hydroxy acids in esterified form, most likely in the form of monohydroxy-acyl-triglycerides. Synthetic glycerides of this type actually showed similar behaviour on heating<sup>1</sup>.

In this communication, observations are described which lend support to the aforementioned assumption. This was obtained by applying thin-layer chromatographic techniques to specific fractions derived from non-heated butterfat.

Our procedure was based on a number of considerations with regard to the  $R_F$ -values to be expected for monohydroxy-acyl-triglycerides as compared with those of mono-, di- and tri-glycerides of normal fatty acids in the systems applied. Thus:

(a) The  $R_F$ -value is about the same as that of a normal diglyceride (Fig. 1, Nos. 1 and 3; in this communication fractions are referred to in order of increasing  $R_F$ ).

(b) The presence of the hydroxy acid moiety in the 1- or in the 2-position could be expected to cause a difference in  $R_F$ -value similar to that observed between those of normal 1,2- and 1,3-diglycerides (Fig. 1, No. 1).

5-g butterfat dissolved in light petroleum/benzene (1:1) was chromatographed on a column filled with a mixture of 30 g 'Silicagel' ('Mallinckrodt', containing 6 per cent physically bound water) and 15 g 'Hyflo' (dried

for 16 h at 120° C). In this way about 80 per cent, consisting entirely of normal triglycerides, was removed. The remainder was eluted with diethyl ether and afterwards chromatographed by thin-layer chromatography on silica, which yielded three main zones, chiefly consisting of mono-, di- and tri-glycerides, respectively (Fig. 1, No. 2).

The silica between the extreme fractions was collected and extracted with ether. On re-chromatographing this fraction (200 mg) on a silica plate using the horizontal developing technique<sup>2</sup>, six fractions A-F were obtained

Fig. 1. Separation of column concentrate of butterfat. 1, Mixture of glyceryl monooleate, 1,2- and 1,3-dioleate and trioleate; 2, 200 mg of column concentrate; 3, 1-mono-(5-hydroxyacyl)-triglyceride. Thickness of silica layer 1 mm, 'Silicagel G' (Merck) purified by extraction with acetone/methanol 1:1 (v/v), eluant iso-octane/ether 60/40 (v/v). Detection with 'Ultraphor'.

Fig. 2. Separation of second concentrate of butterfat. Thickness of silica layer 1 mm, eluant iso-octane/ether 80/20 (v/v). Detection with 'Ultraphor'.

(Fig. 2). Fractions *B* and *F* were found to consist of normal triglycerides, fraction *A* of monoglycerides. Fraction *D* was identified by infra-red spectroscopy as triglycerides containing an acetyl group.

Fraction *B* consisted mainly of 1,3-diglycerides, 1,2-diglycerides and sterols. Because of their  $R_F$ -values, free lactones should also be contained in this fraction (Fig. 3, No. 7). Removal of the lactones was performed by means of thin-layer chromatography on silica after acetylation; they were present in such small amounts, however, that they yielded no visible spot (Fig. 3, No. 8). As a check a synthetic mixture of diglyceride and labelled lactone was acetylated. In this operation, no cross-esterification between the two components was observed. Lactones remain unchanged during the acetylation treatment, as can be seen from Fig. 3, Nos. 1-4.

The acetylated glyceride fraction, now being free from lactones, was saponified, the unsaponifiable part removed and the soap converted into acids. If in this mixture the presence of lactones could be demonstrated, the presence of esterified hydroxy acids in butterfat would be established.

In this we succeeded by first esterifying the acids with diazomethane, followed by acetylation to decrease the polarity of irrelevant hydroxy compounds and afterwards, by separating the mixture by thin-layer chromatography, using a thick silica plate. Only a very weak zone was observed at the site where lactones could be expected on the plate (Fig. 4, zone 3, compare spots 1 and 2 of model 5-decanolide and 4-octanolide). The material extracted from zone 3 was then re-run as a single spot on a thin (0.25 mm) silica plate. When sprayed lightly with a 1 per cent aqueous solution of 'Ultraphor' (BASF) and viewed under ultra-violet light it showed a clear spot at the correct  $R_F$ -value. Moreover, the characteristic lactone smell was clearly noticeable, after extraction of the spot and evaporation to dryness.

Fraction *C* (Fig. 2) was analysed similarly. Free lactones were absent, but—after saponification of the acetylated glycerides—lactones could be detected in the same way as described for fraction *B*.

In both fractions  $\gamma$ - and  $\delta$ -lactones were detected by means of gas-liquid chromatography. Details will be reported elsewhere.

Small differences in  $R_F$ -value of the relevant glycerides in fractions *B* and *C* suggest that in *B* the hydroxy acids are located in the 1-position of the glycerides, whereas in *C* they might occupy the 2-position.

Fig. 3. Influence of acetylation on  $R_F$ -values: 1, 5-decanolide; 2, 5-decanolide after acetylation; 3, 4-nonanolide; 4, 4-nonanolide after acetylation; 5, 1-mono-(5-hydroxyacyl)-triglyceride; 6, 1-mono-(5-hydroxyacyl)-triglyceride after acetylation; 7, fraction *B*; 8, acetylated fraction *B*; 9, acetylated glyceryl 1,3-diolate; 10, cholesterol; 11, cholesterol acetate. Thickness of silica layer 0.25 mm, eluant iso-octane/ether 60/40 (v/v). Detection with molybdophosphoric acid.

Fig. 4. Separation of methylated and acetylated fatty acids of fraction *B*: 1, 5-decanolide; 2, 4-octanolide; 3, lactones; 4, methyl esters of acetylated hydroxy fatty acids; 5, methyl esters of fatty acids. Thickness of silica layer 1 mm, eluant iso-octane/ether 60/40 (v/v). Detection with 'Ultraphor'.

In addition to the occurrence of keto-acid esters described in earlier publications<sup>3,4</sup>, evidence has now been obtained for the presence of hydroxy acid esters in butterfat. Though the overall behaviour observed during the various separation steps strongly suggests the presence of such esters as glycerides, it must be stated that definite proof for the combination with glycerol is still lacking.

### Changes in the Quantity and Nature of Collagen in Rabbit Skin as a Function of Age

THE process of ageing is known to be accompanied by changes in the chemistry of connective tissue. In general collagen seems to accumulate with increasing age. Nevertheless, this is only true for the insoluble fraction, since the soluble collagens, which represent the newly formed molecules, decrease with age, reflecting the lowered rate of synthesis. Most of the work in this connexion has been reviewed in detail by Harkness<sup>1</sup>.

In order to explain this accumulation of collagen which occurs in spite of a decrease in synthesis, we recently examined the turnover of collagen in the skin of growing rats and found it to be an age-dependent process. During periods of rapid growth the turn-over time ( $T_{1/2}$ ) was 28 days whereas as the animal aged it reached 300 days<sup>2</sup>.

In the series of experiments recorded here we intended to evaluate quantitatively the collagen content of the rabbit skin at different stages of development as well as its distribution among different soluble fractions. It was shown by Bakerman, using human skin of different ages, that the amount of collagen extractable by citric acid increased rapidly during foetal development but began to fall exponentially shortly before birth, to reach very low levels in older individuals<sup>3</sup>. In these experiments no distinction was made between the different types of soluble collagens, nor was the total collagen measured.

For the purpose of our experiments rabbits of different ages as well as embryos obtained by Caesarean section were employed. The skin was shaved and, after killing the animals, cleaned from the underlying connective, muscular, and adipose tissues. These as well as all the following steps were performed in the cold (4° C). The skin was afterwards extracted with 0.15 M NaCl, 0.5 M

NaCl and 0.5 M citrate buffer pH 3.6. The insoluble collagen was solubilized by converting to gelatine. All fractions were dialysed as previously described<sup>3</sup>, and hydroxyproline determined in the acid hydrolysate by the method of Woessner<sup>4</sup> adapted to the 'Auto-analyser'. Collagen was calculated on the basis of the hydroxyproline content.

Fig. 1 shows the changes of the insoluble collagen content of rabbit skin as a function of the age of the animal. On the 20th day of gestation, shortly before birth, the skin contains 1.12 per cent insoluble collagen and, as the animal ages, its concentration steadily increases to reach a value of 15.5 per cent in the adult animal.

Fig. 2 summarizes our findings on the collagen distribution among the different soluble fractions. The amount

Fig. 1. Insoluble collagen of rabbit skin at different ages

Fig. 2. Soluble collagen fractions extracted from rabbit skin at different ages

present in the three fractions studied increased with age until the 8th week after birth. At this time the amount extractable by neutral salts began to decline, whereas that soluble in citrate buffer remained constant.

These findings indicate that during the period of maximum growth and rapid rate of collagen synthesis, soluble collagens rapidly build up on their way to becoming insoluble fibrils. As the rate of synthesis of these soluble collagen precursors drops, their pool size decreases due to its rapid turn-over. In the rat we have found a  $T_{1/2}$  of 17-20 days for the 0.15 M and 0.5 M NaCl fractions. The citrate fraction does not act as an immediate precursor, since its concentration does not drop as should be expected if it were being utilized to form insoluble fibres. It seems to reach some kind of equilibrium with the insoluble fraction. This is substantiated by our previous findings using rat skin, where we observed that the turn-over time of the citrate extractable collagen was of the same low magnitude as that of the insoluble collagen.

## PHYSIOLOGY

### Influence of Plasma Urea on Urine Concentration in the Opossum (*Didelphis marsupialis virginiana*)

INCREASING the amount of urea in the plasma has been shown to enhance urine concentration in many mammals (man, cat, dog, sheep, white rat, kangaroo rat, jerboa<sup>1,2</sup>, and rabbit<sup>3</sup>). In some mammals, however, changing the concentration of urea does not affect urine concentration; in the pig, beaver and *Aplodontia*, enhancement does not occur<sup>1,2</sup>. It was hypothesized that the inability of the latter group to raise its urine osmotic ceiling following increases in plasma urea is a primitive condition because these species are relatively primitive, phylogenetically.

The opossum was chosen to test this hypothesis because this species is considered to be one of the oldest living North American mammals and is usually considered to be the most primitive and generalized of living marsupials. With the exception of its larger size, it is apparently very similar to its early ancestors and is considered a 'living Cretaceous fossil'<sup>4</sup>.

Thirteen adult opossums were examined and two or three animals were treated simultaneously. Some animals were tested several times. Urine and plasma osmolalities were determined by a Fiske osmometer following vasopressin injection (1  $\mu$ /kg of body-wt.) during water diuresis according to the method of Dolph *et al.*<sup>5</sup>. Control animals were injected with 1.0 ml. water instead of vasopressin. The delayed response of the opossum to water diuresis and vasopressin required a slight modification of this procedure. Urine samples were taken every 30 min instead of every 20 min and vasopressin was injected when the animal exhibited a urine osmolality hypotonic to that of the plasma. This sometimes required 5 h. The water load was given in two equal portions 15 min apart to prevent regurgitation. Immediately prior to hydration, plasma urea-nitrogen was determined

according to the method of Richter and Lapointe<sup>6</sup> on a Beckman DB spectrophotometer.

Each animal was fed a high- or low-protein diet for a minimum of 14 days prior to treatment. A period of at least 7 days was allowed between treatments of the same animal. The high-protein diet consisted of 80 per cent meat (rabbit muscle and liver) and 20 per cent mixture of powdered milk, cereal, salt, alfalfa meal, and fish oil. The low-protein diet consisted of 90 per cent potatoes and carrots and a 10 per cent mixture containing cornmeal, apples, salt, and lard.

Table 1 presents the U/P ratios which were calculated from measurements taken at the time of peak urine concentration following hydration and vasopressin injection. The opossum can concentrate urine more effectively (U/P 4.75) when fed a high-protein diet than when fed a low-protein diet (U/P 2.32).

Table 1. MEAN URINE (U) AND PLASMA (P) OSMOLALITY AT THE TIME OF PEAK URINE CONCENTRATION FOLLOWING HYDRATION AND VASOPRESSIN INJECTION

Diet	Plasma (mOsm)	Urine (mOsm)	U/P
Low protein (9)	277.6	645	2.32
High protein (7)	281.2	1,354	4.75

\*P < 0.01

No. of observations in brackets.

\* Probability calculated at the 0.01 level of significance using the Mann-Whitney U test.

The urine osmolality of all control animals declined during the experimental procedures. The plasma osmolalities of the two dietary groups before the beginning of experimental procedures showed no significant difference. The plasma urea-nitrogen concentrations in the opossum fed a high-protein diet were significantly higher ( $P < 0.01$ ) than in those fed a low-protein diet (Table 2).

Table 2. MEAN PLASMA OSMOLALITY AND PLASMA UREA-NITROGEN ON DIFFERENT DIETS IMMEDIATELY PRIOR TO HYDRATION

Diet	Plasma (mOsm)	Plasma U/N (mg/100 ml.)
Low protein (11)	323.8	24.9
High protein (10)	326.6	43.2

\*P < 0.01

No. of observations in brackets.

\* Probability calculated at the 0.01 level of significance using the Mann-Whitney U test.

These results show that the maximum urine-concentrating ability of the opossum following vasopressin injection is comparable to that of higher mammals with similar kidney form (Table 3). The relative thickness of the medulla and the maximum urine concentration of the opossum lie between those of the rabbit and the rat, suggesting that the counter-current mechanism in this primitive mammal functions like that of higher mammals. The relative medullary thickness is an indication of the relative length of the loops of Henle, and the greater the relative thickness the greater should be the urine-concentrating ability according to the counter-current hypothesis.

Table 3. COMPARISON OF THE RELATIVE THICKNESS OF THE RENAL MEDULLA AND URINE CONCENTRATING ABILITY FOLLOWING VASOPRESSIN INJECTION

Mammal	Relative thickness of medulla*	Maximum urine concentration following vasopressin injection (mOsm)	Maximum U/P osmolal ratio
<i>Apodonta</i>	2.0	569	1.6
Man	3.0	850	2.9
Dog	4.8	1,875	4.9
Rabbit	5.4	1,045	3.7
Opossum	5.7	1,325	4.75
Rat	5.8	2,636	8.8

\* The medullary thickness  $\times 10$  divided by kidney size; where kidney size equals the cube root of the dimensions of the kidney.

These experiments show that the ability to raise the urine osmotic ceiling following increase in plasma urea is not restricted to higher mammals. The response of the 'primitive' opossum does not support the hypothesis that the inability of a species to raise its urine osmotic ceiling following increases in plasma urea-nitrogen is a primitive condition.

The response of the opossum to urea may be a function of certain anatomical relationships in the kidney. In the renal medulla of the opossum the nephron segments are grouped in such a manner that they form an inner and an outer zone clearly visible in fresh or fixed sections. Zonation of the vasa recta correlated with the zonation due to nephron arrangement is also present in the opossum<sup>8</sup>. Thus, the opossum exhibits characteristics of kidney form and function very similar to those of man, cat, dog, rat, sheep, kangaroo rat, jerboa<sup>1,2,8-10</sup>, and rabbit<sup>1,10</sup>. The beaver, pig, and *Aplodontia*<sup>1,8,11</sup> lack such zonation and they are incapable of raising their urine osmotic ceiling after an increase in plasma urea-nitrogen. It is, therefore, possible that the opossum's ability (and that of other species with similar kidney form) to raise this ceiling after an increase of plasma urea-nitrogen is related to the zonation of nephrons and vasa recta.

Further investigations comparing nephron functions in species showing the zonation described above with nephron function in species with no zonation may help to elucidate the way that urea is handled by the mammalian kidney.

This work was supported by grant HE 08338-01 from U.S. Department of Health, Education and Welfare, Public Health Service, National Institutes of Health.

## Local Control of Luteal Function by the Uterus of the Guinea-pig

THERE is now no doubt that distension of the uterus of a number of species of mammal results in characteristic changes in the oestrous cycle which stem from a shortening of the life span of the corpora lutea in the ovaries<sup>1,2</sup>. Thus in the guinea-pig the presence of two glass beads in each horn of the uterus, when inserted during the first four days after oestrus, shortens the length of the cycle in progress at the time of operation and that of succeeding cycles<sup>3</sup>. The degree to which the cycle is shortened appears to be governed by the number of beads in the uterus, for when one bead is present in each horn the cycle in progress is shortened from a normal length of 16 days to 14 days, whilst when two beads are present in each horn the cycle is reduced to 12 days<sup>4</sup>. Although one bead located in one horn of the uterus of the sheep exerts a definite shortening effect on the oestrous cycle<sup>5</sup>, four beads in one horn of the guinea-pig uterus do not exert as marked an effect as when they are shared between both horns. The mechanism underlying this effect is not understood, although it has been suggested that the pituitary gland is involved in exercising a luteolytic function<sup>6</sup>. The present work has been concerned with the examination of this quantitative effect at the level of the ovaries, and attention directed to the morphological changes taking place in the corpora lutea, rather than to changes in the oestrous cycle over a longer period.

Using the technique of Donovan and Traczyk<sup>7</sup>, one glass bead was inserted into each horn of the uterus of 11 virgin guinea-pigs during one of the first 3 days after oestrus

and ovulation. The animals were killed at various intervals before the next expected oestrus and the ovaries were fixed, histologically processed and sectioned serially at  $10\mu$ . A quantity related to the volume of the corpora lutea in each ovary was estimated by measuring two diameters at right angles in the largest section of each corpus luteum and multiplying the product of these figures by the number of sections of each organ and by the thickness of the sections. No allowance was made for shrinkage during fixation. The results (in  $\text{mm}^3$ ) provided a mean value representing the volume of each corpus luteum ( $D^3$ ) and in this way the changing size of the corpora lutea during the cycle could be followed and compared with the results for normal animals presented by Rowlands<sup>7</sup>. The comparison is illustrated in Fig. 1 and reveals that, while the calculated curve for the growth of the corpora lutea up to the 9th day of the cycle is parallel to that given by Rowlands, there is a marked discontinuity evident on the 11th day. Regression of the corpora lutea appears to have taken place abruptly between the 9th and 11th days, an observation which supports earlier postulations concerning the existence of a process causing degeneration of the corpora lutea following the insertion of beads into the uterus<sup>3</sup>.

In order to examine whether the regression of the corpora lutea is determined by a local rather than by a systemic mechanism, one uterine horn alone was distended and the effect of this procedure on the ipsilateral and contralateral ovary compared. Accordingly 2 glass beads were inserted into the right uterine horn in each of a further 9 guinea-pigs on the second day after oestrus and the animals were killed at various intervals before the next expected oestrus. Histological processing of the ovaries and measurement of the corpora lutea were carried out as before. The results are presented in Table 1, and plotted in Fig. 2. It can readily be seen that the corpora

Fig. 1. The mean volume of the corpora lutea in each ovary plotted against day of cycle for animals bearing one bead in each uterine horn. As the ovaries for each animal were processed together and their left and right individually lost, the data concerning the ovary with the largest corpora lutea ( $\bullet$ ) in each pair were arbitrarily grouped together and compared with their partners ( $\circ$ ) in order to exaggerate any differences. The regression lines for each group are plotted. The broken line indicates the volume/time curve for the corpora lutea of normal animals as calculated by Rowlands<sup>7</sup>.

Fig. 2. The mean volume of the corpora lutea in the ovaries on the operated (—○—) and unoperated (—●—) side of animals bearing two beads in one horn of the uterus. The broken line shows the volume/time curve for corpora lutea in normal animals as calculated by Rowlands<sup>7</sup>.

lutea in the right ovary (associated with the horn of the uterus containing the beads) are significantly smaller than those of the left ( $P < 0.001$ ), indicating that the process initiating regression of the corpora lutea utilizes a local rather than a systemic mechanism. The parallelism observed between the curves for regression of the corpora lutea in each ovary implies that once regression has been initiated (to a greater or lesser degree) it thereafter proceeds at a constant rate.

Table 1. MEAN VOLUME OF CORPORA LUTEA IN INDIVIDUAL OVARIES FOLLOWING DISTENSION OF THE RIGHT UTERINE HORN WITH GLASS BEADS

Animal No.	Day of cycle at autopsy	Mean $D^3$ for corpora lutea of left ovary	Mean $D^3$ for corpora lutea of right ovary	Difference
1003*	8	2.430	2.661	-0.232
1010	10	2.739	1.438	+1.301
1007	10	3.433	2.320	+1.113
1016	11	2.014	1.303	+0.712
916	12	1.908	0.649	+1.259
911	12	2.806	1.045	+1.761
932	12	2.806	0.674	+2.132
973	12	3.779	1.799	+1.980
996	14	1.511	0.870	+0.641

\* Luteal size on day 8 has been omitted from the mathematical analysis due to uncertainty whether at this stage luteal size is increasing or decreasing.

The present findings, though of a preliminary nature, clearly imply the existence of a mechanism through which stimuli originating in one horn of the uterus can promote the regression of the corpora lutea in the ovary on that side. In this connexion it is reasonable to suppose that a luteolytic factor is produced by the uterine horn and could diffuse to the neighbouring ovary. Supporting evidence for this possibility can be drawn from work on hysterectomized animals where, for example, it has been shown that autotransplantation of uterine tissue at the time of hysterectomy prevents the expected persistence of the corpora lutea<sup>8</sup>. In this connexion it is also noteworthy that a close correlation between the presence of uterine tissue and the life of the corpora lutea in the ipsilateral ovary has been shown following sub-total hysterectomy in the pig<sup>9</sup> and guinea-pig<sup>10</sup>. However,

this is the first time that a local effect on the corpora lutea has been observed to follow distension of the uterus and casts doubt on the importance of the pituitary gland in this regard.

We thank the Population Council for support of this work.

## PHARMACOLOGY

### Effect of Dihydrostreptomycin on Tissue Lipid of Guinea-pigs

ANTIBIOTICS are known to have profound effects on nucleic acids and protein biosynthesis. Coniglio and Bell<sup>1</sup> reported that when antibiotics are administered orally to rats there is a significant increase in the incorporation of <sup>14</sup>C-acetate into hepatic fatty acids. Chatterjee *et al.*<sup>2</sup> observed that dihydrostreptomycin significantly influences the lipid metabolism of intestine and whole body of rats. The neurotoxic effects of dihydrostreptomycin on prolonged use in tuberculosis treatment and other infections are well known<sup>3</sup>. The present work was undertaken to study the effects of DHS on lipid changes in various tissues of guinea-pigs.

Female guinea-pigs in groups of four, weighing 350-380 g, were intramuscularly given saline solution of dihydrostreptomycin sulphate (Pfizer) (0.1 g/kg body weight). Guinea-pigs without dihydrostreptomycin served as the controls. After ten days of administration of the drug a saline solution of NaH<sub>2</sub>PO<sub>4</sub> (400 µc/kg body-weight) was given intraperitoneally. The guinea-pigs were killed 6 h after

<sup>32</sup>P administration. Brain, lung, heart, liver, kidney, spleen and adrenals were quickly removed, cleaned, weighed and transferred to a volume of chloroform:methanol (2:1, v/v). The tissues were homogenized in a Potter-Elvehjem homogenizer with 5 volumes of chloroform:methanol (2:1, v/v). Heart and lung tissues were ground with a pestle in a mortar. The lipids from the tissues were extracted with 20 volumes of chloroform:methanol (2:1, v/v) for 4 h at room temperature by the method of Folch *et al.*<sup>4</sup>. The lipid extract was evaporated to dryness *in vacuo* and freed of proteo lipids according to Folch *et al.*<sup>4</sup>. The final lipid residue was dissolved in 5.0 ml. chloroform and used immediately for analysis or stored at -8° in glass-stoppered tubes. All solvents used were of analytical grade and were re-distilled and degassed with nitrogen before use.

The lipid solutions were analysed for cholesterol<sup>5</sup> and phospholipid phosphorus<sup>6</sup>. <sup>32</sup>P activity (c.p.m.) was determined in a TCG-14 Tracer Lab Geiger-Müller tube. The weights of the lipids were determined by weighing 1.0-ml. aliquots to a constant weight. Free and esterified cholesterol were estimated by the digitonin method<sup>7</sup>. The cholesterol on the digitonide was estimated by a method<sup>8</sup> modified from that of Hanel and Dam<sup>9</sup>. The results are shown in Table 1.

From the results (Table 1) it is seen that dihydrostreptomycin does not bring about significant changes in the total lipid contents of any tissues studied. Similar observations are noted in total cholesterol contents of these tissues except in kidney, where dihydrostreptomycin lowers the kidney total cholesterol. An insignificant increase in the free cholesterol of kidney is seen as a result of dihydrostreptomycin treatment, and this finding is in agreement with those of Chatterjee *et al.*<sup>2</sup>. Brain showed a significant decrease in free cholesterol on dihydrostreptomycin treatment, though total cholesterol is not significantly affected. This may possibly be due to some inhibition of cholesterol esterase in brain. Phospholipid phosphorus in brain is significantly reduced in dihydrostreptomycin-treated animals, but it is not affected in any other tissues. Though a decrease in phospholipid phosphorus in brain is seen as a result of dihydrostreptomycin administration, the specific activities (c.p.m./mg P) of brain phospholipids are not significantly affected. The phospholipid phosphorus of heart is not reduced on dihydrostreptomycin treatment, but the specific activities are significantly reduced, indicating a slow turn-over rate of

heart phospholipids. An insignificant increase in total lipid contents and an insignificant decrease in specific activities of phospholipids of adrenals is seen as a result of dihydrostreptomycin treatment. Neither group of animals showed any change in their daily food consumption and body weights.

The results show that brain is the only tissue, where dihydrostreptomycin treatment has significantly lowered both the phospholipid phosphorus and free cholesterol. Whether these observations have any direct or indirect relationship to the neurotoxic effect<sup>3</sup> of dihydrostreptomycin is not certain at present.

### Chronic Toxicity Testing

CERTAIN types of hazard consequent on the administration of chemical substances are estimated by the performance of chronic toxicity tests. Such tests are usually designed according to certain empirical rules. Groups of animals (commonly three) are given a test substance in regularly repeated doses of constant size, each group receiving a different dose; the material can be given either by individual dosing to each animal or by administration in the diet. The interval between doses in the case of individual doses may vary according to the properties of the substance; the most generally used interval is 24 h. The experiment continues for an arbitrarily chosen period of time since no general principle enables the duration of such tests to be determined more rationally.

The results of such tests may be death of the dosed animals or some lesser toxic effect which will occur earlier, and more severely, in the group treated with the highest dose. When toxic effects occur in such experiments certain regularities may be expected; this is because each toxic effect may be considered to have two principal phases—development and restitution. If the interval between two successive doses is too short to permit complete restitution of the previous injury, persistent lesions will develop, accumulate and grow worse. The magnitude of such effects will be related to the size of the individual dose, to the interval between successive doses and to the period over which dosing continues; they will also be modified by such factors as increasing resistance, or sensitivity, to the action of the compound and to the development of secondary factors not primarily related to the injury caused by the compound.

It is well known that the acute biological effects of a single dose of a biologically active substance are related to the logarithm of the dose. It is reasonable to enquire whether, in the circumstances of properly conducted chronic toxicity tests, biological effects are related to time in the same way. It is certainly true that lower doses of a compound will be tolerated for longer periods than larger doses and that some doses can be found, even of very toxic materials, which do not cause overt toxic action in any period of time that can be examined. Such

observations might be expected if effects were related to log time as well as to log dose. If this generalization were true, then there should be a straight-line relationship between the effect and the duration of an experiment when both co-ordinates are logarithmic.

Because chronic toxicity studies are usually terminated at an arbitrary point, it is not easy to obtain sufficient data to support this suggestion. Nevertheless, it is possible to find some examples, two of which are shown in Figs. 1 and 2. Fig. 1 is taken from literature using the data of Hawkins and O'Shanny<sup>4,5</sup> on ataxia occurring in cats

Fig. 2. Time of death in guinea-pigs receiving triphenyl tin acetate in the diet. +, Experiment started March 1962; O, experiment started November 1962

after daily subcutaneous doses of streptomycin. Fig. 2 presents death in guinea-pigs receiving triphenyl tin acetate in the diet.

Other experimental data on chronic toxicity studies with acrylamide (J. M. Barnes, private communication) tend to show the same relationship. Although these experiments were performed simultaneously under different conditions, namely, administration of the substance in daily oral doses, as an ingredient in the diet or in adequate high doses in intervals of a week, the toxic effect, which was weakness of the hind legs, and all the related data fit very well with the foregoing hypothesis.

The principle of accumulation in pharmacology has been examined mathematically by A. J. Clark<sup>1</sup>. Further development of the theoretical background of the kinetics of chronic toxicity by Druckrey<sup>2,3</sup> led to his interpretation of the special conditions in carcinogenicity as the 'summation action' and the 'intensifier action'. In his experiments he could demonstrate an analogous connexion of dose-response and time to that discussed here. In the case of carcinogenic action, however, the conditions are more particular than in the case of the chronic toxicity experiment because there appears to be no repair, the effects of a single action being summated without loss.

If the hypothesis that drug effects are related to the logarithm of the duration of chronic administration as well as to the logarithm of the dose given, the problem of choosing the best duration of a chronic experiment is simplified, and it may also be possible to estimate safe levels of a substance more effectively.

The hypothesis enunciated here suggests several possible experimental tests; since each test is elaborate, any one laboratory can only undertake a very small number.

## HAEMATOLOGY

### Activity of Nicotine and Inactivity of Kallikrein and Kallidin in Aggregation of Blood Platelets

In 1961, Gaarder *et al.*<sup>1</sup> reported that adenosine diphosphate (ADP) causes human blood platelets to aggregate. Born *et al.*<sup>2,3</sup> described a method by which the aggregation of platelets may be followed quantitatively. They confirmed the results of Gaarder and described inhibition of the ADP-effect by 2-chloroadenosine and other substituted nucleosides<sup>4</sup>. Lately, some more results on this subject have been published<sup>5-7</sup>, but the mechanism of platelet aggregation is still unknown.

Recently we described release of 5-hydroxytryptamine (5-HT) and other biogenic amines from isolated rabbit blood platelets by nicotine<sup>8,9</sup>; Singh and Oester<sup>10</sup> reported that nicotine lowered coagulation time *in vivo* with concomitant release of epinephrine, and Wenzel and Singh<sup>11</sup> showed that intravenous injection of nicotine or epinephrine reduces coagulation time in rabbits. Damage of arterial walls and formation of thrombi in rabbits brought about by epinephrine, acetylcholine, 5-HT, several polypeptides and inhalation of cigarette smoke can be prevented by nialamide<sup>12</sup>. Investigations on the influence of these substances on platelet aggregation *in vitro* should therefore contribute to knowledge of the mechanism involved.

We therefore tested nicotine, 5-HT and iproniazid with respect to an eventual effect on platelet aggregation using the slightly modified method of Born and Cross<sup>3</sup>.

Gokeen and Yunis<sup>13</sup> presented strong evidence that fibrinogen is involved in platelet structure, using trypsin and other proteolytic enzymes. Kallikrein, which resembles trypsin in many respects, was not studied. Kallikrein has proteolytic and esterolytic properties and produces the polypeptide kallidin, which is strongly hypotensive<sup>14-16</sup> and enhances the permeability of membranes and capillaries.

To investigate the possibility that kallikrein may influence platelet aggregation by an effect on platelet membrane structures, we tested kallidin and kallikrein. The latter was investigated with special regard to the fact that inability of coagulation due to fibrinolysinaemia may be treated successfully with a kallikrein inhibitor<sup>17-19</sup>.

By measuring the optical density at 600 mμ of platelet-rich mechanically stirred rabbit blood plasma we tested the platelet aggregation with results shown in Fig. 1.

Under our conditions ADP causes the platelets rapidly to aggregate. Nicotine causes aggregation of platelets dependent on the concentrations used, but relatively high nicotine concentrations are needed. When nicotine and ADP were added simultaneously the effects of both enhanced each other. Kallikrein (up to 10 units/3 ml. plasma) and kallidin (15 and 90 units/3 ml. plasma) had no effect and did not influence platelet aggregation elicited by ADP. Iproniazid  $5 \times 10^{-3}$  M inhibited the action of ADP and nicotine. 5-HT had no measurable effect, either alone or in combination with ADP. Thioglycolic acid (0.05 ml.), which prevents breakdown of kallidin by kallidinase<sup>20</sup>, had no influence on the negative results obtained with kallikrein and kallidin, but totally prevented the aggregation induced by ADP. (After completion of this investigation Jokay *et al.*<sup>21</sup> have reported thioglycolic acid and other thiol compounds to inhibit the endotoxin induced platelet aggregation and the simultaneous release of histamine and 5-HT.)

Our results confirm the findings of Gaarder *et al.*<sup>1</sup>, Born *et al.*<sup>2,4</sup> and Shimamoto<sup>18</sup>. The aggregation of platelets by nicotine may be caused by a change of the electrical charge of the thrombocyte membrane, because there is

Fig. 1. Effect of ADP, nicotine and iproniazid on the aggregation of rabbit blood platelets as measured by optical density of platelet-rich rabbit blood plasma at 600 mμ.  $\Delta$ , ADP  $1 \times 10^{-3}$  M + nicotine  $5 \times 10^{-3}$  M;  $\bullet$ , nicotine  $5 \times 10^{-3}$  M;  $\square$ , ADP  $1 \times 10^{-3}$  M;  $\triangle$ , nicotine  $1 \times 10^{-3}$  M after iproniazid  $5 \times 10^{-3}$  M;  $\circ$ , ADP  $1 \times 10^{-3}$  M after iproniazid  $5 \times 10^{-3}$  M.

strong evidence that nicotine may enhance the permeability of the platelet membrane by changing its charge. Nicotine could cause aggregation by releasing ADP; this, however, seems unlikely, because a very similar compound ATP is not released from platelets by nicotine<sup>21</sup>.

### Iron Studies of Thalassemic Erythrocytes after Splenectomy

DURING the past few years, the uptake of iron by immature red cells *in vitro* has been studied extensively. Studies have included the kinetics of stromal iron as well as of intracellular iron. Thus Tishkoff<sup>1</sup> measured stromal iron after intravenous injection of <sup>59</sup>Fe in thalassemic patients and also in patients with other diseases. Allen and Jandl<sup>2</sup> studied the kinetics of intracellular iron in an *in vitro* system, using reticulocyte-rich rabbit red cells incubated with <sup>59</sup>Fe-labelled plasma, and measured the <sup>59</sup>Fe in the stroma, mitochondria, and microsomes. Clark<sup>3</sup> used radioactive iron *in vivo* and *in vitro* to measure the stromal iron in rat red cells. Falbe-Hansen and Lothe<sup>4</sup> studied the stromal iron in rabbit red cells after intravenous injection of <sup>59</sup>Fe.

In a previous study from this laboratory, it was found that after incubation of thalassemic blood with <sup>59</sup>Fe, the radioactivity associated with the stroma was greater than in normal blood<sup>5</sup>. The difference was statistically significant after 6 h incubation, but was not statistically significant after 1 h. This finding was considered to indicate some retention of iron by the stroma of the thalassemic red cells. The beneficial results of splenectomy in thalassemia led us to extend our studies to the red cells of splenectomized thalassemic patients. The uptake of iron by the stromal fraction after incubation of blood with <sup>59</sup>Fe has been compared with that observed in thalassemic patients without splenectomy.

Fourteen thalassemic subjects with splenectomy were studied. The haematological and other data concerning the patients are shown in Table 1.

The method used for the iron uptake by immature red cells was similar to that described previously<sup>6</sup>. The method of Tishkoff *et al.*<sup>1</sup> was used for the separation of the stroma of the red cells.

The <sup>59</sup>Fe content of the stromal fraction is expressed as a percentage of the total <sup>59</sup>Fe taken up by the immature red cells. The results are given in Table 2. In Table 3 the

6	57.2		26.7					24.4
13	56.7	47.3				20.5		
14			46.2		30.3			28.9

mean values of the stromal <sup>59</sup>Fe are compared for thalassemic patients with and without splenectomy. The values from the thalassemic patients without splenectomy are taken from the published data of Malamos *et al.*<sup>4</sup>. Three of these cases were studied also *in vivo*. The results are summarized in Table 4.

The results summarized in Table 3 show that the <sup>59</sup>Fe associated with the stromal fraction is greater in erythrocytes from splenectomized thalassemic patients than in those from thalassemic patients without splenectomy. This difference is statistically significant ( $P < 0.001$ ).

It is known that after splenectomy there are morphological changes in the blood elements, such as the appearance or the increase of nucleated red cells in the blood stream, the increase of reticulocytes, the appearance of siderocytes, Howell-Jolly bodies and Hainz bodies, as well as changes in the surface area, which becomes larger than before without any change in the cellular volume<sup>7,8</sup>.

It is possible that the increase in the number of circulating nucleated red cells after splenectomy, as well as the change in their shape, may affect the <sup>59</sup>Fe content of the stromal fraction. Another possible explanation is provided by the appearance in the blood stream of large numbers of siderocytes, in which the incorporated iron is not used for haemoglobin synthesis, but is thought to be deposited in the stroma or in the mitochondria. Thus Hoffman *et al.*<sup>9</sup> have described a new high-density particle in the stroma of thalassemic erythrocytes. Beasis and Breton-Gorins<sup>10,11</sup> have shown by electron microscopy that iron-containing granules are present in normal erythroblasts, normoblasts

and reticulocytes and also in certain pathological erythrocytes. They found that in thalassaemia, 80 per cent of the erythrocytes had iron-containing granules. In thalassaemia also large quantities of iron in the form of ferritin were seen in the mitochondria of nearly all polychromatophilic and acidophilic erythroblasts. Larizza and Orlandi<sup>12</sup> have also found by electron microscopy that marrow siderocytes show accumulation of iron in the mitochondria. Tishkoff<sup>1</sup> found that the stromal iron of erythrocytes was moderately increased in two patients after splenectomy and he considered it a reflexion of the siderocytosis.

It is considered that the appearance of siderocytes in the blood after splenectomy is due to the absence of the "pitting function" of the spleen<sup>7,13</sup>. An increase of stromal <sup>59</sup>Fe after intravenous injection of <sup>59</sup>Fe in splenectomized thalassaemic patients could possibly be explained by the absence of the "pitting function" of the spleen. This opinion is supported by the fact that after intravenous injection of <sup>59</sup>Fe the radioactivity associated with the stromal fraction in thalassaemic patients without splenectomy is low, amounting to only about 2-5 per cent of the radioactivity of the erythrocytes (our unpublished data). On the other hand, in thalassaemic patients with splenectomy the values are high, as illustrated by the three cases of the present study (Table 4).

However, absence of the "pitting function" of the spleen cannot explain the increased <sup>59</sup>Fe in the stromal fraction after incubation with <sup>59</sup>Fe of blood from splenectomized patients. In one case (No. 4 of Table 2) the values for stromal <sup>59</sup>Fe (studied *in vitro*) before and after splenectomy were 21 per cent and 51 per cent respectively.

The observed increase of stromal <sup>59</sup>Fe after *in vitro* incubation is not specific for splenectomized thalassaemic patients, but is a phenomenon observed also in other splenectomized subjects. In pyridoxine deficiency anaemia, sickle cell thalassaemia, Hb E/thalassaemia and myelodysplasia we have observed values of 55, 59.6, 72.2 and 43.9 per cent, respectively, for <sup>59</sup>Fe in the stromal fraction.

It is suggested by Dameshek<sup>14</sup> that the spleen acts as an endocrine organ and releases a humoral factor which affects erythropoiesis. Such a humoral factor has not been isolated. However, whether or not there is a humoral factor released by the spleen affecting erythropoiesis, it is probable that the role of the spleen in erythropoiesis is fulfilled not only by its pitting function but also in some other way.

We thank Dr. E. Harries for her advice.

## HISTOLOGY

### Argentaffin Cell Incidence in the Rectal Mucosa of Man, Mouse, and Hamster

THE often quoted standard work on the argentaffin cell by Jacobson in 1939<sup>1</sup> is doubtless the source cited by many authors on the distribution of argentaffin cells. From it we quote, "In man and all animals investigated, there appears to be a steady decrease in the number of (argentaffin) cells towards the caudal end of the intestine. The rectum of cattle seems to be an exception to this rule".

This communication reports quantitative work on the frequency of argentaffin cells within human rectal mucosa as compared with mouse and hamster rectal mucosa. The rule set out by Jacobson was not borne out and there were exceptions not only for cattle but, to a greater degree, for man. In addition, data for two animal species have been quantitated to provide an accurate index of the low incidence of these cells per crypt rather than per unit area as reported by investigators prior to Jacobson.

Eleven biopsies were performed on patients at Bellevue Hospital with no illness related to the gastrointestinal tract. Three one-year-old female Swiss hybrid mice from the Charles River animal farm and four Syrian hamsters, two years of age, from the Lakeview hamster colony in New Jersey were killed and the rectum was dissected out for histological study. All material was fixed in 10 per cent formalin and stained using the Schmorl and Diazo technique as described by Pearce<sup>2</sup>. Sections were cut at 5μ for the human material and at 5 or 10μ for the mouse and hamster material. Insufficient material from one patient made it impossible to obtain a Schmorl reading.

As many crypts as possible were scored for the number of argentaffin cells present in each crypt in the human material. As few as 61 crypts were scored for a given stain reaction because of the scarcity of the biopsy material, but at least 50 per cent of the human data is based on more than 100 crypts. In the case of hamster and mouse material, at least 200 crypts were scored (Table 1). The argentaffin cell values are expressed as the number of cells per crypt for each individual sampled; the mean argentaffin cell value is given with the standard error of the mean.

As seen from Table 1, the mean number of argentaffin cells for human rectal material was approximately two per crypt although the average per person varied between one and three per crypt. Age did not appear to account for the variability in argentaffin cell number between adults tested.

Table 1. ARGENTAFFIN CELL INCIDENCE IN MAN, MOUSE AND HAMSTER

3		200	9 0.05	200	20 0.10
4		200	2 0.01	400	0 0
		Mean 0.06 ± 0.02		Mean 0.06 ± 0.0	

While the average was found to be between one and three cells per crypt, it was not very unusual to see as many as ten or more argentaffin cells present in one crypt (Fig. 1). It is true that while many of these cells are found at the base of the crypt, they are frequently seen at some distance from the base, migrating to the surface. In fact, they are occasionally seen close to the surface and lumen of the crypt (Fig. 2). Although these cells are described as seldom found together and occurring singly between the other cells<sup>2</sup>, in human rectal mucosa, it was not uncommon to find large clusters of these cells at the base of the crypts, lying one beside the other (Fig. 1).

The results of the analysis of the frequency of argentaffin cells in mouse and hamster rectum appear in Table 1. An argentaffin cell may be seen in approximately one out of three rectal crypts in the mouse, and more nearly one for every 20 crypts in the hamster. Although quantitation of the argentaffin cells in the rectum of mouse and hamster was difficult because they were not numerous,

Fig. 1. Base of several rectal crypts in a human biopsy specimen, with ten argentaffin cells in one crypt and many of these cells in one cluster (top left). Bohm method ( $\times 700$ )

Fig. 2. Three argentaffin cells at the upper portion and near the lumen of a human rectal crypt. Diano method ( $\times 700$ )

Table 2. DISTRIBUTION OF ARGENTAFFIN CELLS IN 5 CM OF RECTUM FROM VARIOUS SPECIES (according to Tehver<sup>4</sup>)

Species	Samples	Argentaffin cells
Dog	5	0
	1	0
Cat	2	0
	1	20
	1	24
Cow	1	120
	1	210
	1	165
Calf	1	0
	1	140
	1	70
Horse	1	0
	1	9
Pig	1	0
	1	43

the figures measure their relatively low incidence, which was reproducible in both 5- $\mu$  and 10- $\mu$  sections.

There are enough data to demonstrate that argentaffin cells are not rare in human rectal mucosa. They are at least five times as numerous as in the mouse and forty times more frequent than in the hamster. The figures reported by Tehver in 1930<sup>4</sup> for cattle seem large when compared with the figures obtained in dog, cat, horse and pig (Table 2), but he examined 5 cm of rectum in 10- $\mu$  sections. Our data are derived from specimens of human rectal mucosa not more than 1-2 mm long. 5 cm of bovine rectum or 1-2 mm of human rectum contained 120-210 argentaffin cells.

Throughout the course of this study the nucleus of only one argentaffin cell was thought to be in mitosis. The loss of these cells due to their migration up the crypt must require them to be replaced in a manner similar to the epithelial cell. Their relative frequency in human rectal mucosa suggests that this tissue, obtainable at biopsy, would provide suitable material for investigation of their renewal.

This investigation was supported in part by Public Health Science Program—project grant AM 06284 from the National Institute of Arthritis and Metabolic Diseases.

## PATHOLOGY

### Haemolytic Activity of Suspensions of Different Silica Modifications and Inert Dusts

RECENTLY, Harley and Margolis<sup>1</sup> reported haemolytic activity of amorphous silica particles of sizes larger than 5  $\mu$ . In the course of an investigation on the possible role of complement (C') in the cytotoxicity of quartz, our experiments revealed a specific haemolytic effect of buffered saline suspensions of this mineral. Using corundum ( $\alpha$ - $\text{Al}_2\text{O}_3$ ) and anatase ( $\text{TiO}_2$ ) of the same surface area as quartz, significantly less haemolysis was found<sup>2</sup>.

Since haemolysis is a simple model for the damage of the membranes of cells and sub-cellular particles, several mineral dusts which had been checked previously for fibrogenic effects in animal experiments<sup>3,4</sup> were tested for their haemolytic activities.

Six different modifications of silica were used in these tests: quartz prepared by grinding pure rock crystal from Brazil to a respirable size less than 2  $\mu$  (corresponding to a specific surface area of 6.5  $\text{m}^2/\text{g}$  of the final powder); vitreous silica prepared by grinding pure fused silica to

8.8 m<sup>2</sup>/g; cristobalite prepared by sintering vitreous silica in presence of a mineralizing reagent and afterwards grinding to 9.7 m<sup>2</sup>/g; tridymite prepared as in the case of cristobalite, specific surface area 7.2 m<sup>2</sup>/g; coesite (14.1 m<sup>2</sup>/g) and stishovite (21 m<sup>2</sup>/g) isolated from Coconino sandstone of Meteor Crater near Winslow, Arizona<sup>5</sup>. Two commercial types of alumina ('Degussa Al 23 VT',  $\alpha$ -Al<sub>2</sub>O<sub>3</sub>, 13.8 m<sup>2</sup>/g, and 'Degussa Aluminiumoxid P',  $\gamma$ -Al<sub>2</sub>O<sub>3</sub>, 86 m<sup>2</sup>/g) and one of TiO<sub>2</sub> (anatase, 'Kronos A', Titangeellschaft Leverkusen, 8.6 m<sup>2</sup>/g) were used as inert dusts, that is, dusts showing no significant fibrogenic effects.

Specific surfaces were determined by means of argon adsorption (Brunauer-Emmett-Teller method).

Human and sheep red cells were washed three times in isotonic saline (pH 7.4, barbital buffer). Samples were prepared from the aforementioned dusts, each with a surface area of 0.02 m<sup>2</sup>. To 0.5 ml. saline suspensions of each of these samples were added 0.5 ml. of 3 per cent red cell suspensions. These mixtures were incubated each for 1 h at 37° C. Cells and dust particles were kept in suspension by gently agitating the test-tubes every 5–10 min. Four ml. amounts of saline were added to every tube, and the optical density measured at 550 m $\mu$  after centrifuging (2,000 r.p.m., 5 min).

As shown in Table 1, all silica modifications except stishovite have a much higher haemolytic activity than the pathologically inert dusts, based on the surface area of the dust particles in suspension. The haemolytic activity fairly parallels the fibrogenic effect in animal experiments; this is especially clear-cut in the case of stishovite, the only non-silicogenic crystalline silica modification<sup>6</sup>.

The haemolytic action of quartz is suppressed by preincubation of mineral powder in a solution of polyvinylpyridine-*N*-oxide (P 204), a compound that shows an antisilicogenic effect in animal experiments<sup>7</sup>. Haemolysis is diminished to varying degrees by coating the quartz with trimethylsilyl-groups<sup>8</sup>, alumina<sup>9</sup>, gelatine, cholesterol, and a lipid extract from erythrocyte stroma<sup>3</sup>.

In another series of experiments the samples of dust were increased with respect to surface area. The results (Fig. 1) demonstrate that haemolysis increases with the surface of the dust.

In experiments fully reported elsewhere<sup>3</sup> practically no additional haemolysis was observed if dilutions of homologous serum (1 ml.) with complement titres up to 30 C' H<sub>50</sub> units were added to red cell suspensions (0.5 ml.) that had been in contact with a limited amount of quartz that lysed less than 50 per cent of the cells.

It can be assumed that the mechanism of the lysis of erythrocytes by the crystalline silica modifications tested involves the adsorption of lipids from the erythrocyte

Fig. 1. Abscissa, m<sup>2</sup> total surface area of dust particles brought in contact with 1 ml. 3 per cent human red cell suspension in buffered saline; ordinate, percentage haemolysis. 1, Quartz; 2, coesite; 3, corundum; 4, stishovite; 5, anatase

membrane similar to what Brown<sup>9</sup> has reported for the amorphous silica preparation, 'Hyflo Super Cel'. The composition of erythrocyte lipids adsorbed by these crystalline silica modifications is under study.

The agreement of the results from the model of haemolysis *in vitro* with those from animal experiments<sup>3,4</sup> indicates that damage of subcellular structures is the specific step in the silicotic process. All membranes including those of mitochondria are composed of substantial amounts of lipids<sup>10</sup>, as are microsomes.

Damage of these structures in the phagocyte would inhibit simultaneously the oxidation processes as well as protein synthesis and result in necrobiosis, and in the increased turn-over of macrophages characteristic for early stages of silicotic lesions, as released dust particles are newly phagocytosed.

## Time-course Concentration of N-Acetylneuraminase Lyase from Rat Granulation Tissue

The time sequence of enzymatic and metabolic alterations during inflammatory response and repair by connective tissue has been inadequately studied. Enzymatic changes related to connective tissue and the inflammatory process are virtually unknown. However, observations during the development of the chick embryo<sup>1</sup> and of

biological development of tissue-specific proteins and metabolic adaptations in response to environmental effects or with ageing<sup>4</sup> suggest that similar events are operative when injury occurs and inflammation and repair are initiated by connective tissue.

The metabolism of *N*-acetylneuraminic acid (*N*-AN) is presumably of importance in inflammation. This was suggested by the finding of a *N*-AN-containing glycoprotein fraction in an inflammatory tissue<sup>5</sup>. Lyases which cleave *N*-AN aldolytically have been isolated from *Cl. perfringens*<sup>6,7</sup> and from rat kidney cortex, and in addition demonstrated in a variety of other animal tissues<sup>8</sup>. Pathways for the biosynthesis of *N*-AN have also been clearly established<sup>9-11</sup>. The purpose of this communication is to demonstrate an enzyme system from experimental inflammatory tissue which yields pyruvic acid from *N*-AN and which varies in activity within the tissue with time.

Air-turpentine pouches were prepared in male albino rats, weighing approximately 200 g, of the Sprague-Dawley strain<sup>12</sup>. Granulation tissue was allowed to develop for periods of 3-16 days. A complete series of tissues at different phases of development could not be run simultaneously, but various stages were studied in duplicate, and replicate observations were obtained at various time intervals. For each analysis, the granulomata from 2 to 4 rats were dissected from the skin and the finely minced tissue was washed twice with a buffered salt solution (100 volumes 0.15 M KCl, 5 volumes 0.15 M MgSO<sub>4</sub>, 20 volumes 0.1 M potassium phosphate buffer, pH 7.4 with cysteine. HCl was added to a concentration of 10<sup>-3</sup> M). The washed mince, averaging approximately 7 g per rat, was weighed and homogenized in a 'Virtis 45' apparatus with 2 volumes of the buffered salt solution for 30 sec. The brei was centrifuged at 2,200g for 15 min and the supernatant decanted through double-thickness gauze after removal of the lipid pellet. All preparations were maintained at 0° C. Samples containing 0.7 ml. of the resulting homogenate were incubated with shaking with 3 μmoles of *N*-AN (isolated from human meconium<sup>13</sup>) and 15 μmoles potassium phosphate buffer, pH 7.2 in a final volume of 1 ml. 37° for 30 min. After incubation inactivation was accomplished by heating in a rapidly boiling water bath. Appropriate aliquots of the incubation mixture, cleared by centrifugation at 16,000g after addition of 'Celite', were analysed for pyruvic acid spectrophotometrically using lactate dehydrogenase (Boehringer) and DPNH (Pabst). The methods employed were those of Comb and Roseman<sup>8</sup> with minor modification. The protein concentration of each homogenate was determined by a biuret method<sup>14</sup>. Each series of incubations was run in duplicate with appropriate controls. The average variation of enzyme activity for multiple extractions was ± 6.3 per cent with a reproducibility of multiple determinations from a single extract of ± 14.1 per cent. The production of pyruvate from *N*-AN was linear with respect to protein concentration.

The observed data suggest that the enzyme activity of 7-day granuloma tissue is greater than that obtained from tissues of other ages. Although certain overlaps in the ranges of activity occurred it was clear that the maximal enzyme activities with respect to tissue weight and maximal specific activity were observed at 7 days. Fig. 1 graphically illustrates the results.

The accounts of enzyme variation or adaptation, which have been referred to, demonstrate some correlation between the differentiation of tissues and their specific function. Quite often, however, changes in enzyme patterns could only be related to the age of the tissue. Even in the face of rapid structural and morphologic changes in the granulation tissue<sup>15,16</sup> the factors controlling *N*-AN lyase activity remain obscure. Time-course studies of guinea-pig granulomata concerning changes in DNA, collagen and ascorbic acid indicate that on or about the seventh day of induction there is a rise in DNA and collagen content<sup>17</sup>. A fucose-containing glycoprotein fraction also

Fig. 1. *N*-Acetylneuraminidase lyase activity in granulation tissue of varying ages. The top graph represents changes in total activity of the enzyme per g of tissue expressed as the amount of pyruvate formed in 30 min. The lower graph represents changes in enzyme activity per mg of protein incubated with age of granulation tissue. Mean values are indicated by continuous traces.

changes in concentration with respect to time<sup>18</sup>. Seven-day rat granulomata contain significant concentrations of an *N*-AN-containing glycoprotein material<sup>5</sup> as well as a number of acid mucopolysaccharides<sup>19</sup>. The metabolism of these biopolymers is very likely controlled by an intricate series of reactions as suggested by other experiments<sup>17-19</sup>. *N*-AN lyase is probably an active step in the catabolism of *N*-AN rather than its biosynthesis<sup>4-9</sup>. This report is a further demonstration of the complex and rapid but defined biochemical changes occurring in inflammatory tissue.

## RADIOBIOLOGY

### Tritium-labelled Peptide Hormones with High Specific Radioactivity

PRESENT interest in the assay of peptide hormones has led to the development of radio-immunoassay methods. These are based on the competition for antibody by labelled and unlabelled hormones, and the subsequent separation of antibody-bound from 'free' radioactivity<sup>1</sup>.

<sup>125</sup>I-labelled hormones have the practical disadvantage of the short eight-day half-life of <sup>125</sup>I, and the theoretical disadvantage that iodination tends to destroy the biological potency of the hormones. With these considerations in mind, we have prepared tritium-labelled hormones of high specific activity using the technique of acetylation. In general, between 0.2 and 1.0  $\mu$ moles of hormone are mixed with 25 mc. (7  $\mu$ moles) tritiated acetic anhydride (3,570 mc./mmole from Nuclear Chicago Corporation) in 0.25 ml. water saturated with sodium acetate and adjusted to pH 8.0–8.5 with 0.1 N NaOH. The acetylated hormone is then separated from the free acetate by passing the mixture through a 2  $\times$  15 cm 'Sephadex G-25' column. With this technique we have prepared tritium-labelled human growth hormone (3.2 acetyl/mole, 275  $\mu$ c./mg) tritium-labelled bovine growth hormone (12 acetyl/mole, 570  $\mu$ c./mg), and tritium-labelled pork insulin (127  $\mu$ c./mg, 0.5 acetyl/mole). Human and bovine growth hormone acetylated to this extent with <sup>14</sup>C-labelled acetic anhydride have previously been demonstrated to be biologically and antigenically comparable with unlabelled hormone<sup>1,2</sup>.

## BIOLOGY

### Rate of Greying of Human Hair

GREYING of hair is probably the most obvious sign of ageing in man. To determine whether or not its onset and progress are influenced by hair colour we have examined a sample of Australians.

Blood donors were readily available to us. Their use had, however, a disadvantage, since we had to restrict their examination to simple inspection. More accurate methods, involving the taking of hair samples, were impracticable. In these conditions, assessment of degrees of greying presented problems which were not satisfactorily solved. We first prepared for use as standards a series of coloured photographs, illustrating hair of different shades with increasing degrees of greying. But matching the photographs with living subjects was unsatisfactory. We then mixed samples of cut hair of different colours with increasing proportions of white hair, but again matching was difficult. Finally, we decided to rely on the observers' judgments in recording only two categories of greying. Those subjects with any visible grey or white hair were designated 'any greying'. Those with no discernible hair of the original hue were classed 'complete greying'.

The total number examined was 8,720, comprising 6,653 men and 2,067 women. Colour of the hair was judged by simple inspection. If the hair was completely grey or white, or suspected of being tinted or dyed, the subject's own statement regarding the true colour and the degree of greyness was accepted. Preliminary trials showed the observers to be in substantial agreement and their findings concerning the distribution of hair colour agree closely with those in a recent survey in Victoria, Australia<sup>1</sup>.

Only subjects aged twenty-five years or more are included in this report. Younger persons were excluded for these reasons. Few young Australians of either sex

wear hats. All are heavily exposed to direct sunlight. Many also use bleaches to obtain the desired combination of heavily tanned skin and very fair hair. It was therefore often difficult in the young to determine the true hair colour or to distinguish between naturally and artificially produced loss of pigmentation.

The age incidence of greying in men and women, judged by these criteria, is shown in Table 1. The minor differences between the sexes are not significant. For any greying,  $P < 0.30 > 0.20$ ; for complete greying,  $P < 0.50 > 0.30$ . In considering the possible influence of hair colour on greying the data for both sexes have therefore been combined.

Table 1. GREYING AS RELATED TO SEX AND AGE

Age	No.		Any greying (%)		Complete greying (%)	
	M	F	M	F	M	F
25+	2,574	698	23.29	23.85	0.23	0.14
35+	2,157	627	61.38	66.35	2.18	1.59
45+	1,493	553	88.68	88.25	12.50	9.95
55+	429	159	94.16	96.20	22.91	23.57

The age incidence of greying as related to hair colour is shown in Table 2. The data for fair and red hair have been pooled, as there was no significant difference between them. Inspection of Table 2 shows a paradoxical situation. If the first indication of greying is the criterion, greying appears sooner in dark than in fair hair and more dark than fair-haired subjects showed some greying. But more fair than dark-haired subjects were classed as completely grey.

Table 2. AGE INCIDENCE OF GREYING IN RELATION TO HAIR COLOUR

Age	At risk			Any greying (%)			Complete greying (%)		
	Fair	Med- lum	Dark	Fair	Med- lum	Dark	Fair	Med- lum	Dark
25+	502	839	454	4.6	10.4	25.4	0.4	0.0	0.0
30+	345	674	459	18.0	23.3	40.5	0.6	0.3	0.2
35+	333	666	444	37.2	53.2	64.0	0.9	1.2	1.1
40+	303	604	474	60.5	71.4	74.9	4.6	3.3	1.9
45+	283	510	406	84.0	83.3	90.4	8.9	8.6	8.4
50+	205	331	313	92.7	91.2	93.3	22.9	15.4	12.8
55+	137	222	198	96.4	93.2	94.9	43.3	31.1	19.2
60+	16	26	18	100.0	100.0	100.0	50.0	23.1	16.7
Totals	2,063	3,972	2,765	45.8	52.9	68.1	7.6	5.2	3.3

The explanation for this apparent contradiction may be found in the relatively crude method of observation. A few white hairs will stand out more distinctly against a background of dark than of fair hair. Conversely, a few dark hairs will be more noticeable against a grey than a dark background. The first signs of greying will therefore be seen most readily in dark hair; but fair hair will appear to have turned completely grey sooner than dark.

If this be so, one might question whether these results have any objective value. However, further analysis provides an interesting result. The age-incidence data in each colour-class can be satisfactorily fitted to straight lines, using the log-probit transformation (Table 3). The regression lines are parallel within each colour-class, but the slope is steeper for fair than for dark hair.

Table 3. GREYING IN RELATION TO HAIR COLOUR (Log-probit regressions)

Colour	Degree of greying	Probit	$\chi^2$	d.f.	P
Fair	Any	4.753 (in age)—12.439	5.093	6	< 0.70 > 0.50
	Complete	4.753 (in age)—14.489	6.171	4	< 0.20 > 0.10
Fair	Any	3.667 (in age)—8.910	8.539	6	< 0.30 > 0.20
	Complete	3.667 (in age)—11.243	6.144	6	< 0.50 > 0.30
Medium	Any	3.351 (in age)—6.659	7.280	6	< 0.30 > 0.20
	Complete	3.351 (in age)—9.397	5.667	5	< 0.50 > 0.30
Dark	Any	3.351 (in age)—6.659	7.280	6	< 0.30 > 0.20
	Complete	3.351 (in age)—9.397	5.667	5	< 0.50 > 0.30

Since the regression lines for minimal and maximal greying within each colour-class are parallel, let us assume that a parallel line midway between them represents the proportion of subjects in whom at least half the hair has turned white or grey. This class may be conveniently designated 'at least 50 per cent greying'. The three mid-lines so constructed have a common intersection. The calculated ages at which 50 per cent of the population at risk are 'at least 50 per cent grey' are 48.6 years for fair

hair, 49.4 years for medium hair, and 49.1 years for dark hair. For this sample it seems a fair approximation to say that at 50 years of age 50 per cent of people are at least 50 per cent grey, irrespective of sex or hair colour. The good fits in the log-probit transformations indicate that susceptibility to greying is normally distributed.

It seems probable that the rate at which the pigmentary content of human hair diminishes is independent of the initial concentration, but that visual impressions of degrees of greying are strongly influenced by the contrast between the original colour and white.

### Strange Male Block to Pregnancy: its Absence in Inbred Mouse Strains

A SERIES of papers by Bruce and colleagues<sup>1-4</sup> has described a pre-implantation block to pregnancy in non-inbred laboratory mice which is evoked by the presence of strange males of the same strain or of a different strain ('alien' males). This effect is olfactory-mediated. The phenomenon has also been reported in another species, non-inbred prairie deer mice (*Peromyscus maniculatus bairdii*)<sup>5</sup>.

We felt that the physiological mechanisms involved in this phenomenon could be studied most effectively using highly inbred strains of mice, both because of a high degree of genetic control and because strains might differ in manifestation of the pregnancy block. Therefore a preliminary survey was made of the capacity for implantation to be blocked by strange or alien males in a number of inbred strains.

Experimental procedure for blocking implantation was as follows: females were paired individually with stud males of the same strain in the morning. All females were examined for the presence of a vaginal plug on the following four mornings. The stud male was removed from the home cage of a female after she showed a vaginal plug, and a 'strange' male of the same strain or an 'alien' male of a different strain was introduced. The strange or alien male was removed after 48 h, and all inseminated females were autopsied seven days after insemination to determine if implantation had occurred. In controls the stud male was removed, and the female remained isolated for the entire 7-day period until autopsy.

Five strains were tested. Although the data are not exhaustive with respect either to experimental design or to sample size, there was no indication that the pregnancy block was operating in any of the strains, in females exposed either to strange or to alien males (Table 1). Probability testing was by  $\chi^2$  and there were no significant differences between controls and experimentals within any of the strains.

It is perhaps premature to speculate extensively as to why the inbred strains that were tested failed to show the

pregnancy block. An inability of the females to discriminate between strange and stud males of such close genetic similarity could explain the results of within-strain testing. However, attempts to prevent implantation with alien males of a strain different from the stud male were equally unsuccessful. It is impossible to determine from the data whether blocking capacity is absent in males, females, or both.

Because of the many problems in reproduction that usually arise during intensive inbreeding, naturally occurring mechanisms that interfere with reproduction might be selected against in efforts to maintain a productive inbred line.

This study was supported in part by U.S. Public Health Service research grants 5T1 OA 5013 from the National Cancer Institute and HD-00767 from the National Institute of Child Health and Human Development.

### A New Record for *Leptopenus*, a Rare Deep-water Coral

AMONG the rarest of the deep-water corals are specimens of *Leptopenus* (family Microbaciidae). At present the only records of this delicate coral I have verified are those of the *Challenger Expedition*<sup>1</sup>, which took 5 specimens from 4 localities, all from depths in excess of 2,700 m. Reported occurrences of the genus off the South Australian coast<sup>2</sup> are probably incorrect and are more possibly worn specimens of *Leptosammia*, another microbaciid coral. The Vero Collection examined by Dennant cannot now be located (F. McNeill, *in lit.*), but specimens of *Leptosammia* have been taken from South Australia in comparable depths<sup>3</sup>.

The rarity of this coral and the great depths from which it has been recorded make additional specimens very significant. Only one coral, *Fungiacyathus marenzelleri*<sup>4</sup>, has been recorded from greater depths (5,868 m). The family Microbaciidae, in its evolution, shows progressive adaptation to life in deeper waters from *Microbacia*, through *Stephanophyllia* and *Leptosammia* to *Leptopenus*, at the end of the series. In this genus skeletal structures are greatly reduced with the result that a striking corallum is formed.

The specimen described here was taken from greenish clay at 2,000 m in Makassar Strait (*Galathea* Station 453, 3° 58' S., 118° 28' E.). The specimen is the central part of the corallum and was dead when collected. Maximum diameter of the fragment is 6.0 mm and its height is 2.5 mm. Septa are reduced to spines, with particularly stout and elongate spines developed over the delta formed by the union of septa of the first, second and third cycles (Fig. 1).

*Leptopenus discus* is the best known of the two species of *Leptopenus* described by Moseley<sup>5</sup>, being represented by four specimens taken from three localities:

*Challenger* Station 147: 46° 16' S., 48° 27' E., 80 miles west of Hog Island, Crozet Islands, 2,926 m.

*Challenger* Station 157: 53° 55' S., 108° 35' E., southern Indian Ocean, 3,566 m.

*Challenger* Station 323: 35° 39' S., 50° 47' W., east of Rio de la Plata, 3,475 m.

*L. hypocoelus* is known from a single specimen from *Challenger* Station 299; 33° 31' S., 74° 43' W., off Valparaiso, Chile, at 3,950 m.

Table 1. THE PERCENTAGE OF PREGNANCIES ON DAY 7 POST INSEMINATION IN SELECTED STRAINS OF INBRED HOUSE MICE EXPOSED TO A STRANGE OR ALIEN MALE FOR TWO DAYS AFTER INSEMINATION OR TO ISOLATION

Strain	Control	Strange male	Alien male
057BL/6J	86 (56)	89 (72)	90(41) CBA/J
CBA/J	89 (9)	100 (21)	—
CBA/Os	100 (23)	96 (26)	—
SWR/J	93 (27)	93 (27)	—
129/J	71 (33)	61 (52)	68(25) CBA/J or 057BL/6J

Figures in parenthesis give the numbers of mice in the sample.

Fig. 1. A reconstruction of the central portion of the corallum of *Leptopenus* taken by the *Galathea* collection, x c. 7. Drawing by Miss Caroline Bartlett

The *Galathea* specimen is probably the central part of the disk-like corallum of *L. discois*. This species has a recorded diameter of 25 mm; but the central spinose portion of the corallum appears to be about 5 mm in diameter, judging from Moseley's illustrations. The maximum height of the *Challenger* specimens is stated to be 2 mm. In the *Challenger* specimens, the remainder of the corallum is formed by a broad, nearly flat structure which is exceedingly fragile and would easily be broken in life or in the process of collection.

This new record is an extension of the known range considerably to the north, and is the shallowest occurrence of the species. Neither the location nor the depth is surprising for a poorly known organism and, of course, the depth records of the *Challenger* in deeper waters are questionable because they were wire soundings.

I thank Drs. Torben Wolff and Jensenius Madsen for permitting me to examine the important collection of deep-water corals made by the *Galathea* Expedition. This work is part of a larger investigation of the corals of the Southern Ocean, supported by National Science Foundation grant GB-353.

### Toxicity of Dieldrin and Endrin to Bats

IN the course of our investigation of the storage and mobilization of lipids and pesticides in Chiroptera, it became necessary to obtain some data regarding the toxicity of various insecticides to bats. In a previous paper we reported that the big brown bat, *Eptesicus fuscus*, was extremely sensitive to DDT<sup>1</sup>. This communication reports the responses of this animal to two additional chlorinated hydrocarbon pesticides.

The bats were captured during August 1964 in attics of houses in Georgetown and St. Helens, Kentucky. On arrival at the laboratory they were weighed, banded and put into individual cages consisting of wide-mouthed gallon jars containing a bedding of wood shavings covered with filter paper. A small dish of water was provided. Each animal was fed about 3-5 g of bat 'glop', a blend of

equal parts of ripe banana, cream cheese, canned dog food and adult meal worms, *Tenebrio molitor*, a day. A period of 24 h was allowed for acclimatization to laboratory conditions. Technical-grade dieldrin and endrin were dissolved in corn oil and the calculated quantities administered in single dosages directly on to the food as the bats ate while being held in the hand. Bats took both glop and corn oil avidly. Controls were fed corn oil in a quantity equivalent to the largest dosage of oil given the experimental animals. The bats were observed at hourly intervals during the first day and at intervals of 24 h or less thereafter. The experiment was terminated after 28 days.

\* Tremors never observed.

† Released in apparent good health at end of experiment.

Results of the experiment are shown in Tables 1 and 2. In the case of dieldrin, deaths occurred at all doses of 20 mg/kg and above. The apparent  $LD_{50}$  is of the order of 70 mg/kg. The approximate  $LD_{50}$  seems to be in the range 20–40 mg/kg. This is not greatly different from the toxicity of dieldrin to the white rat for which the  $LD_{50}$  is reported as 46 mg/kg (ref. 2).

With endrin mortality was noted at doses as low as 4 mg/kg. The  $LD_{50}$  as seen in this experiment was 12 mg/kg, although there was one survivor at 20 mg/kg. The results indicate an approximate  $LD_{50}$  in the range of 5–8 mg/kg. Hayes<sup>3</sup> reported the  $LD_{50}$  as 7.8 mg/kg and 17.8 mg/kg for the female and male white rat, respectively.

Thus the toxicities of dieldrin and endrin are rather comparable in bats and rats. These pesticides do not show the relatively high toxicity to big brown bats that was demonstrated with DDT. This is of interest in that it suggests that the response of bats to DDT is not simply due to their unique heterothermic metabolism.

### Recording Leaf Movements with a Strain Gauge

In our pilot studies concerning the effect of space environments on the circadian leaf movements, we have devised a small lightweight leaf movement recording system using a strain gauge coupled to an amplifier and a recorder. The need for such a system was dictated by the physical limitations of an orbiting capsule. We have also found that such a system is useful for earthbound experiments. The small size of the sensing unit makes it possible to place several units on a single plant. The monitored plant can easily be placed in a small control chamber and continuous records of several weeks' duration can be obtained when the movements are recorded on a strip chart recorder.

The active element of the leaf movement sensing unit is a strain gauge  $\frac{1}{8}$  in. wide and  $\frac{1}{4}$  in. long. The gauge (EA-09-031DE-120) is made by Micro-Measurements, Inc., Romulus, Michigan. In our experiments, the strain gauge was glued with Eastman '910' adhesive to the centre of a brass shim stock, 0.001 in. thick,  $\frac{1}{8}$  in. wide and  $1\frac{1}{2}$  in. long. The brass shim is formed into a half loop with  $\frac{1}{4}$ -in. tabs at the ends of the half loop. One of the tabs is glued to the leaf petiole and the other to the midrib of the leaf blade with polyvinylacetate ('white glue') (Fig. 1). In the amounts used, the glue was not toxic to the plant organs. The strain gauge is part of the bridge circuit that is supplied with d.c. voltage. The signal generated by the movements of the leaf blade is sent to the amplifier of the Minneapolis-Honeywell Brown recorder and the amplified signal is recorded on the strip chart.

The recording system proposed for the orbiting system has the same bridge configuration but has a Philbrick Researches solid-state amplifier 'PP85A' instead of the recorder amplifier (see Fig. 2). The voltage supply to the amplifier derives its power from a 22.5–45.0 V portable 'B' battery and the voltage is regulated at 15.0 V by the 'IN965' Zener diodes. The differential signal output of this smaller system is at least 0.2 volts with a leaf de-

Fig. 1. Leaf movement sensing unit. The unit is glued to petiole and midrib of a pinto bean leaf.

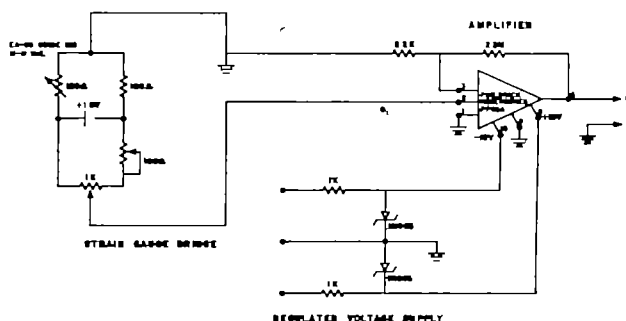

Fig. 2. Leaf movement recording circuitry. The system has 3 sections: (1) Bridge circuit with a strain gauge as the leaf movement sensing unit. (2) Amplifier unit with a Philbrick P85A or PP85A unit wired for 1,000 × amplified output. (3) Regulated voltage supply limited by IN965 Zener diodes.

flexion of around 30°. The weight of this system less power supply is about one ounce and the dimensions are  $\frac{1}{2}$  in. by 1 in. by 2 in.

The sensing unit was tested for temperature effects and for voltage change effects. When the ambient temperature was varied from 27° to 45° C, the leaf angle readings on the Brown recorder varied 2°. Thus a 1° C change in ambient temperature resulted in an error of 0.11° in the leaf angle reading. This error is considered negligible for our work since the temperature variation on our growth chamber can be kept down to  $\pm 0.2^\circ$  C. As a further refinement, the substitution of another strain gauge for the 120-ohm resistor in the bridge will eliminate this error. The inert substituted gauge will act as a standard control. A voltage variation of 1.0 V supplied to the strain gauge resulted in an error of 10.0° in leaf angle reading. However, the voltage supply can be regulated to within  $\pm 0.02$  V under most conditions and the resulting leaf angle error will only be  $\pm 0.2^\circ$ . This error is considered negligible for our experiments.

To test the reliability and accuracy of the system, the strain gauge unit was attached to a primary leaf of a pinto

Fig. 3. The curve shows the relation between strain gauge record and kymograph record taken simultaneously from same leaf. Actual leaf angle is given at the right. Horizontal position is given a value of 90° and vertical down position is given a value of 180°. Dotted line depicts the ideal correlation curve.

been. A kymograph was also attached to the same leaf and four days of records were obtained. The kymograph recorded the leaf movements by means of a leverage system that had the leaf attached by means of a thread to one end and a pen to the other end. The pen produced a permanent record on a chart calibrated to read out the leaf angles directly. The chart was wrapped around a drum that turned once a week. The strain gauge signals were recorded on the M. H. Brown strip chart recorder. The results of the strain gauge records were compared with the records of the kymograph. The time sequence of the peaks and dips of the two records were identical. On further examination it was found that the leaf angle values were not directly correlated between the strain gauge records and the kymograph records. On plotting the corresponding points of the kymograph and the strip chart records, it was found that the maximum deviation of the strain gauge records was not more than 5° from the values of the kymograph records (see Fig. 3). Since the peaks and dips on the curves are not displaced in time sequence we feel that the deviation is not large enough to invalidate the strain gauge records for cycle-length studies.

This unit is being used in experiments testing the effects of light-dark cycles on the leaf movements of pinto beans.

We thank Dr. Robert Chipman, Mr. Raymond Kado and Mr. Stanley Noguchi for their assistance and advice. We also thank Dr. J. D. French for his help. The work was supported by the National Aeronautics and Space Administration grant NAG 528 and U.S. Air Force grant AF-AFOSR 246-63.

### *Bathycorixa thalassina* (Herrich-Schaeffer), (Hemiptera: Pentatomidae); a Pest of *Theobroma* *cacao* L.

LARGE nymphs and adult *Bathycorixa thalassina* (Herrich-Schaeffer) have recently been found to feed on developing cocoa pods, causing damage to the beans; the small nymphs feed mainly on the leaves and do little damage. The adults have long feeding stylets (about 2.2 cm) which can penetrate the pod cortex (see Fig. 1) and suck liquid from the developing beans; this results in malformed or atrophied beans. In ripe pods the malformed beans are brown instead of pink, and dry, lacking the sugary mucilage which normally covers beans.

The damage is often not evident externally in harvested pods apart from small black spots formed at the feeding

Fig. 1. Sectioned cocoa pod: damaged tissue (top left) shows the path of feeding stylets of *B. thalassina*. Pod diameter about 6 cm.

Fig. 2. Damage to young pods results in distorted mature pods often with a 'waist'. Amazon pod, 12 cm long.

lesions. But pods damaged at an early stage fail to swell where the beans have stopped developing, and show a characteristic distortion when fully developed, often in the form of a constriction or 'waist' in the middle of the pods (see Fig. 2).

In some harvests in early 1964 from plots at the Cocoa Research Institute of Ghana more than 20 per cent of the pods were damaged, and all the beans in some pods were imperfect. Damage to the total crop from the Institute was small, but *B. thalassina* populations were first noticed to be high in 1962 and may still be increasing. This species was found on cocoa in several parts of Ghana and at Ibadan in Nigeria in March, 1964.

*B. thalassina* has been reported to feed on cocoa pods in the Congo<sup>1</sup> and Cameroons<sup>2</sup>, causing very small pods to shrivel and fall, but causing negligible damage to full-sized pods; the beans were not affected.

## ENTOMOLOGY

Hatching Pattern of *Aedes aegypti* Eggs

DURING their work on the effect of ultrasonic waves on the hatching of *Aedes aegypti* eggs Quraishi *et al.*<sup>1</sup> found an interesting pattern of hatching in the controls. *Aedes aegypti* eggs laid overnight were kept in water in Petri dishes and the percentage of larvae hatching out each day was recorded for 20 days. On the first day 2.5 per cent of the eggs hatched out; on the second day this percentage was 18, the highest recorded for any single day. The percentage of eggs hatching out gradually decreased after the second day, until after the 18th day, when there was an upward trend in hatching, and a small peak was discernible between the 14th and 16th days. There was a sudden fall in the number of eggs hatching out after the 16th day and by the 20th day only 0.2 per cent of the eggs hatched out. Thus 37.5 per cent of apparently normal eggs were left unhatched. We therefore decided to follow the hatching pattern of *Aedes aegypti* eggs for 50 days.

Fresh and well-formed eggs laid during the previous night were selected early in the morning and were divided into batches of 50 each and kept in Petri dishes, 13.5 cm in diameter, containing 75 ml. tap water. A few mg of yeast in tablet form was added to each dish and the dishes were kept in incubators at  $88^{\circ} \pm 2^{\circ}$  F. They were taken out for half an hour every 24 h for observation. The first, second, and subsequent days were counted as 24, 48, etc., hours after the eggs had been selected; since at the time of selection the age of these eggs was already 0-16 h, the time lapse will be number of days plus 0-16 h. Fifty replicates were done and the data are thus based on 2,500 eggs.

The pattern of hatching is shown in Fig. 1. Four peaks in the pattern of hatching are easily discernible; the first peak, which is also the highest, appears on the second day and is followed by a much smaller peak between the 14th and 16th days. Very few larvae hatch out after the 18th day, though some larvae come out each day. An upward trend in hatching is again discernible between the 20th and 23rd days representing a third peak which is smaller than the second. Between the 23rd and 43rd days only a few eggs hatch out, not more than 0.2 per cent of the total on any one day. On the 44th and 45th days, however, 0.2 per cent and 0.76 per cent of the eggs hatch out, representing the fourth and smallest peak.

After the completion of this work in Karachi, Pakistan, I worked in Tehran, Iran, and maintained another colony of *Aedes aegypti* from a local strain obtained from the Institute of Parasitology and Malariology, University of Tehran. Although only a few observations were made, a similar pattern of hatching with four peaks was observed. The last peak in this case was also observed on the 45th day.

The occurrence of four hatching cycles, each succeeding one smaller than the previous one, in the eggs of an insect

Fig. 1. Hatching pattern of *Aedes aegypti*

the larvae and pupae of which are entirely aquatic, is evidently an adaptation to meet the exigencies of a situation where the first few showers may not provide enough water for the completion of the entire aquatic cycle.

This work was done while I was working as senior scientist in the Pakistan Council of Scientific and Industrial Research and in the CENTO Institute of Nuclear Science, Tehran. I thank Dr. S. Siddiqui, Dr. I. H. Usmami and Dr. M. L. Smith for advice, and Mr. Wahajuddin Roomi and Mr. A. B. M. Lutful Kabir for their help. Dr. Ch. M. H. Mofidi provided the eggs of *Aedes aegypti* in Tehran.

Rearing *Pieris brassicae* L. Larvae on a Semi-synthetic Diet

A METHOD for breeding *Pieris brassicae* L., the large white butterfly, all the year round has been developed<sup>1,2</sup>, and the larvae have proved to be convenient insects to use for insecticidal tests and other investigations. However, in severe winters cabbage and kale leaves are killed by frost and it becomes difficult to provide food for large numbers of larvae. One possibility, namely using the heart leaves of cabbage from clamps<sup>3</sup>, has not proved to be satisfactory. Furthermore, for investigations on pathogens, it is desirable to have a food which can be sterilized.

Recently Ignoffo<sup>4</sup> described a medium for the mass rearing of *Trichoplusia ni* Hübner, the cabbage looper, which is a modification of that developed by Vandervant and Reiser<sup>5,6</sup>. We have slightly modified this medium and have shown it to be satisfactory for rearing *P. brassicae*:

Formula of medium.

(a) Distilled water	110 ml.
Potassium hydroxide 4 molar	1.6 ml.
Oasein (light white soluble)	12.6 g
(b) Sucrose	12.6 g
Wheat germ ('Bemax')	10.8 g
Cabbage (dried powder)	5.4 g
Salt mixture	3.6 g
Whatman, chromedia cellulose powder, CF11 grade	1.8 g
(c) Choline chloride (10% soln.)	3.6 ml.
Methyl parahydroxy-benzoate (15% in 95% EtOH)	3.6 ml.
Formaldehyde soln. (10% w/v soln.)	1.5 ml.
Vitamin stock	0.8 ml.
(d) Distilled water	200 ml.
Agar (fine Japanese powder)	9 g
(e) L-Ascorbic acid	1.5 g
Aureomycin (veterinary grade)	0.8 g

The composition of the salt mixture (in g) is:  $\text{CaCO}_3$ , 120;  $\text{K}_2\text{HPO}_4$ , 120;  $\text{CaH}_2\text{PO}_4$ , 20;  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ , 40.8;  $\text{NaCl}$ , 67;  $\text{FeSO}_4 \cdot 6\text{H}_2\text{O}$ , 11;  $\text{KI}$ , 0.32;  $\text{MnSO}_4 \cdot 4\text{H}_2\text{O}$ , 2.0;  $\text{ZnCl}_2$ , 0.10;  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ , 0.12.

The composition of the vitamin stock (in mg) is: nicotinic acid 600; calcium pantothenate, 600; riboflavin ( $\text{B}_2$ ), 800; ascorbic hydrochloride ( $\text{B}_3$ ), 150; pyridoxine hydrochloride ( $\text{B}_6$ ), 150; folic acid, 150; D-biotin, 12; cyanocobalamin ( $\text{B}_{12}$ ), 1.2; 100 ml. water.

The dried cotton leaf in the original medium (about 1.4 per cent wt.) was replaced by dried cabbage leaf powder. This was prepared by drying cabbage leaves in thin layers in a ventilated oven at  $105^{\circ}\text{C}$  for 15-20 min. The leaves can then be ground by hand with a roller and sieved through a 60-mesh sieve, but it is much quicker, of course, to have them ground in a small Christy-Norris mill fitted with a 0.5-mm mesh screen. The veterinary grade aureomycin soluble powder (Cyanamid of Great Britain) contained 25 g chlortetracycline hydrochloride per pound.

The ingredients listed in (a) are placed in a blender with a capacity of 800 ml. and thoroughly mixed together. The mixed solids (b) are then added with further blending. The solutions (c) are next added, separately, while the blender is running. Meanwhile, the agar solution (d) has been prepared in a water bath. It is cooled to  $70^{\circ}\text{C}$  and added to the mixture. Finally, the ingredients (e) are added and the whole medium is thoroughly blended.

The warm medium was poured into sterilized 1 lb. jam jars to a depth of about 0.5 in. and while still warm each jar was tipped and twisted so as to coat some of the sides. As soon as the medium was cool the jars were turned upside down to prevent unnecessary contamination. They can be conveniently stored at about 12° C. After the larvae were introduced the jars were kept on their sides so that comparatively little frass fell on the medium. Whatman No. 1 filter paper was first used to close the jars as this reduced evaporation and prevented the medium drying out too rapidly, but when the larvae reached the fifth instar the paper was changed for a piece of 'Terylene' gauze as more ventilation was now necessary to prevent conditions in the jars becoming too humid and sticky. About 15 fifth instar larvae can be kept in a jar and of course more younger larvae.

For smaller numbers of young larvae it saves medium to use 2 in. x 1 in. specimen tubes containing about half-an-inch of medium. These tubes can be filled rapidly from a warm water-jacketed dispenser that has been developed. After covering with filter paper the tubes may be stood upside down, either directly on a tray or on gauze, if more ventilation seems necessary. The small, light, plugs of medium seldom fall away from the bottoms of the tubes as is very liable to happen if the 1 lb. jars are kept upside down.

In order to obtain a good rate of growth and normal adults we have found it advisable to supply freshly made medium at about weekly intervals. This was necessary because the medium dried out and possibly because of the growth of contaminating organisms.

On medium (changed weekly) the development from hatching to pupation took about 1-2 days longer than on good cabbage leaves. The yield of pupae, based on the number of first instar larvae, has reached 100 per cent and is usually above 80 per cent. Of these pupae, up to 100 per cent have given normal adults. Pupal weights of larvae bred on medium (average 0.37 g) tend to be just below those of larvae fed on cabbage (average 0.38 g). The adults mated normally and the eggs were fully fertile.

Besides being useful for rearing larvae in winter the medium has other advantages. It provides a more standard diet, it is less likely to be contaminated by pathogens since during the drying process virus and other organisms on the cabbage will be destroyed, it greatly facilitates the counting and examination of young larvae since they are much more easily seen than among leaves, and, finally, it would be more convenient for use by laboratories in cities.

### Development and Characterization of Resistance to o-Isopropoxyphenyl Methylcarbamate in the Mosquito *Culex pipiens quinquefasciatus* Say

THE possibility of development of resistance to carbamate insecticides in mosquitoes, and the character of such resistance, are questions of profound importance in the vector control and eradication programmes of public health agencies. With the gradual elimination of organochlorine insecticides in many parts of the world due to

development of resistance, attention has been directed to substitute insecticides, particularly in the organophosphorous and carbamate groups<sup>1,2</sup>. Resistance to certain organophosphorous insecticides has already appeared in strains of *Culex* and *Aedes*, especially in areas where these compounds have been used routinely as larvicides<sup>1,3</sup>. This phenomenon has created even greater urgency for research into the resistance potential of mosquitoes to the carbamate insecticides.

For the past four years we have been investigating the development of resistance in *Anopheles albimanus* and *Culex pipiens quinquefasciatus*, through selection pressure with m-isopropylphenyl methylcarbamate ('Heracles' AC-5727). Interim progress reports on this work have been published<sup>4,5</sup>. Selection pressure on the above species for 21 and 50 generations, respectively, did not materially enhance their tolerance to the selective agent. The observed shift in the dosage-mortality regression lines represents an increase in tolerance of only 2.7 and 2-fold, respectively. Although very encouraging, these results were only of academic interest since the carbamate used appears to have no commercial possibilities due to its high mammalian toxicity.

More recently our attention has been directed to a related carbamate, 'Bayer 89007' (o-isopropoxyphenyl methylcarbamate), which is of considerably lower mammalian toxicity (oral, rats, 175-200 mg/kg). A strain of *Culex pipiens quinquefasciatus*, containing both DDT- and dieldrin-resistant individuals was colonized from Southern California, and subjected to larval selection pressure with the above carbamate at approximately the  $LC_{50}$  level. Resistance increased rapidly in the first selected generation and more slowly thereafter, reaching a 10.75-fold level in the 17th generation. The  $LC_{50}$  values of the parental and  $F_{17}$  generations were 0.29 and 3.12 p.p.m., respectively ( $b$  values 3.42 and 9.04, respectively).

The cross-resistance characteristics of the selected strain toward various carbamate and organophosphorous insecticides are shown in Table 1. It is evident that certain specificity of the resistance mechanism exists for the *ortho* substituted phenyl methylcarbamates (compounds VII, VIII, XI); this specificity appears to be of low level, however, since cross-resistance extends also to a variety of other carbamates as well as to the organophosphorous insecticides malathion and fenitrothion. Similarly there was a small intensification of the initial DDT and dieldrin resistances of the parental strain.

Table 1. RESPONSE TO VARIOUS INSECTICIDES IN SUSCEPTIBLE AND RESISTANT<sup>a</sup> LARVAE OF *Culex pipiens quinquefasciatus*

Compound	Susceptible strain $LC_{50}$ (p.p.m.)	Resistant strain Resistance ratio†
Methylcarbamate

<sup>a</sup> Selected with o-isopropoxyphenyl methylcarbamate

†  $LC_{50}$  Resistant strain

$LC_{50}$  Susceptible strain

A substrain separated from the  $F_7$  selected generation and reared without pressure for an additional 10 generations revealed the stability of the character of resistance. The  $LC_{50}$  values of the  $F_7$  and the  $F_{17+10}$  (unselected) generations were 2.16 and 1.50 p.p.m., respectively ( $b$  values 8.61 and 8.46, respectively).

The metabolic efficiency of the resistant and susceptible strains was compared by the use of <sup>14</sup>C-labelled o-isopropoxyphenyl methylcarbamate. Groups of 30 fourth-

instar larvae were exposed for 2 h to a concentration of 10 p.p.m. of the labelled carbamate; they were afterwards homogenized, extracted with acetonitrile, chromatographed on propylene glycol paper, and tested for radioactivity on an automatic scanning device ('Vanguard Autoscaner 880'). The relative proportion of metabolites recorded was 12.4 per cent in the susceptible strain and 30.4 per cent in the resistant; this amounts to an increase of 2.5-fold in carbamate detoxication efficiency of the resistant strain.

The genetic basis of resistance to *o*-isopropoxyphenyl methylcarbamate was investigated by testing the offspring of reciprocal crosses between the susceptible and resistant strains. Resistance in the  $F_1$  generation was intermediate. The observed responses of the  $F_1$  and back-cross generations were significantly different from those which could be expected on the basis of monofactorial inheritance. The proportion of fully susceptible and fully resistant individuals segregating in the  $F_2$  was consistently below expectation. It was, therefore, concluded that resistance to *o*-isopropoxyphenyl methylcarbamate in our strain of *Culex*, at its present level of resistance, is controlled by a polygenic system.

This investigation was supported in part by U.S. Public Health Service grant GM 11880-01, from the National Institute of General Medical Sciences.

## MICROBIOLOGY

### Functional Homology of the Sex-Factor and Resistance Transfer Factors

DRUG-RESISTANT bacteria can emerge from sensitive populations by acquiring a 'resistance factor' ( $R$ -factor)<sup>1,2</sup> from another strain by conjugation. Genetically, an  $R$ -factor behaves as an extrachromosomal structure<sup>3</sup> belonging to the same class of elements as the transmissible sex-factor ( $F$ )<sup>3,4</sup> of *Escherichia coli*, and its derivatives (designated  $F'$ ) in which a fragment of bacterial chromosome has become associated with  $F$  (ref. 5). In an  $R$ -factor a collection of genes determining resistance to one or as many as six different drugs is transferred as a single unit of inheritance linked to a resistance transfer factor ( $RTF$ ) responsible for the transmission<sup>6</sup>.

Cells carrying  $F$  or  $F'$  factors are recognized by their ability to conjugate and donate chromosome to female ( $F^-$ ) cells, in which genetic recombination may then occur. Bacteria with  $F$  or  $F'$  produce a specific antigen absent from  $F^-$  cells<sup>7</sup> and are sensitive to a group of  $F$ -specific RNA phages which do not attack  $F^-$  cells<sup>8</sup>. These properties suggest that  $F$  determines the formation of a surface structure responsible at the same time for (a) conjugation, (b) serological specificity, and (c) uptake of specific phage; the phage receptor has in fact been identified as a specialized pilus<sup>9</sup>. Despite the overall similarity of the  $F'$  and  $R$  factors, they differ in certain important respects which has generally been taken to mean that the respective fertility factors,  $F$  and  $RTF$ , are not the same: (1) conjugation occurs much less frequently with  $R$  than with  $F$ , as measured by the frequency with which each is transmitted; (2) chromosomal transfer with  $R$  occurs at a very low frequency, if at all<sup>6</sup>; (3) the  $F$  antigen is apparently absent from  $R^+$  cultures<sup>10</sup>; and (4) such cultures are apparently insensitive to the  $F$ -specific phage<sup>11</sup>. Moreover,

(5) with some exceptions<sup>12</sup>, the  $R$ -factor inhibits the expression of  $F$ : when  $R$  is introduced into a cell which is already  $F^+$ , the properties of the cell dependent on  $F$  disappear, and only reappear when the  $R$ -factor is lost<sup>11,12</sup>.

The apparent distinctions between  $RTF$  and  $F$  could alternatively be explained by supposing that the two factors are really identical except in one respect—that whereas the fertility functions of  $F$  are normally expressed in the majority of an  $F^+$  population, those of the  $RTF$  are expressed in only a small minority of  $R^+$  bacteria. Furthermore, it can be postulated that this restriction of  $RTF$  function is due to a repressor, made by  $RTF$  but not by  $F$ , but which can also act on  $F$  when both factors are present in the same cell. Evidence that there is repression of this sort comes from the behaviour of cells which have only recently acquired an  $R$ -factor<sup>14</sup>. Such cells transmit the factor with much greater frequency than cells which have carried it for many generations, indicating that there is a lag between the cell acquiring the  $RTF$  and the development of its repressor.

Even if the bacterial surface characters determined by  $RTF$  and  $F$  were identical, the fact that  $RTF$  is normally only rarely expressed would be enough to account for the reported failure of the  $F$ -phage to lyse or to adsorb to  $R^+$  cultures. Two sorts of experiment were therefore done: (1) to look for a minute proportion of cells sensitive to the  $F$ -phage in established  $R^+$  cultures; and (2) to find out if this proportion is greatly increased in a high-frequency resistance transfer ( $HFR$ ) culture which has just received the  $R$ -factor by conjugation. An  $HFR$  system consists of broth inoculated with a small number of established  $R^+$  cells and a much larger number of  $R^-$  cells through which the factor can spread.

The presence of small numbers of cells capable of propagating a phage can be detected by adding a known quantity of the phage and looking for a subsequent increase in titre<sup>15</sup>.  $F$ -specific phage was added to  $F$ -cultures of *E. coli* K12, infected and uninfected with  $R$ -factor, and assayed at intervals. From preliminary experiments without antiphage serum, we concluded that sensitive cells, if present, must be in such small numbers that they could only be detected if residual unadsorbed phage was eliminated. To achieve this, and at the same time to maintain a high bacterial concentration, the bacteria were mixed with a 20–100 fold excess of phage for a short time (10–15 min at 37° C) in tryptone broth containing M/500 calcium chloride, which these phages require for optimal infection of  $F^+$  bacteria<sup>16</sup>. The mixture was then diluted into antiphage serum from which the antibacterial antibodies had been absorbed, and after a further 10 min, the bacteria were collected and washed on a membrane filter which was then rinsed in a flask of broth. (Control counts showed that virtually all the bacteria were recovered by this technique.) The flask was assayed for phage immediately and again after 2-h incubation, using a standard indicator strain (*E. coli* K12  $HfrB1$ ), which gave entirely reproducible plaque counts on plates incubated at 42° C (ref. 17). The small proportion of residual unneutralized phage particles not eliminated by antiserum and filtration was measured by including a control suspension of  $F^-R^-$  bacteria which had been boiled for 10 min. After allowing for this, the number of plaques in the initial count should measure the number of infectable bacteria. This proved to be negligible in some cultures, which could mean that sensitive bacteria were either totally absent or present only in very small numbers. These two possibilities were distinguished by the second assay made 2 h after infection: in the absence of sensitive bacteria, the plaque count should not increase, but, since these phages have a very large burst size of  $10^3$ – $10^4$ , the presence of even a few sensitive cells should be detected. The results of the second assay showed that phage always increased in the  $R^+$  cultures, but never in  $R^-F^-$  strains (see Table 1).

The same experiment made with  $HFR$  mixtures gave spectacular results: it was clear that these unrepressed

Table 1. REACTIONS OF  $R^+$  CULTURES WITH  $F$ -SPECIFIC PHAGE

Bacteria	Initial plaque count	Plaque count after 2 h	Increase $\times$
711 ( $K12 F^-$ ) budded	$1.7 \times 10^6$	$1.9 \times 10^6$	—
711 ( $K12 F^-$ )	$8.9 \times 10^5$	$7.0 \times 10^5$	—
711 + $R_{H_1}$	$1.4 \times 10^6$	$1.5 \times 10^6$	$1.1 \times 10^6$
711 + $R_{H_2}$	$1.2 \times 10^6$	$1.9 \times 10^6$	$1.5 \times 10^6$
J8 ( $K12 F^-$ )	$7.7 \times 10^5$	$7.5 \times 10^5$	—
J8 + $R_{H_1}$	$1.6 \times 10^6$	$2.4 \times 10^6$	$1.5 \times 10^6$
J8 + $R_{H_2}$	$1.7 \times 10^6$	$1.9 \times 10^6$	$1.1 \times 10^6$
HFR $\pi$ mixture*	$3.1 \times 10^6$	$5 \times 10^6$	$1.7 \times 10^6$
711 $R_{H_1}$ + 711			
HFR $\pi$ mixture†	$3.4 \times 10^6$	$2.9 \times 10^6$	$8.5 \times 10^4$
711 $R_{H_2}$ + 711			
$K12 HfrB1$ ( $F^+$ indicator)	$8.4 \times 10^5$	$1.0 \times 10^{11}$	$1.2 \times 10^5$

The bacterial strains were all derivatives of *E. coli* K12. The  $R$ -factors,  $R_{H_1}$  and  $R_{H_2}$ , found in naturally-occurring drug-resistant salmonellae, were transferred directly to these strains by mixed culture.  $F$ -specific phages  $\pi$ 52 and  $\pi$ 2 were used, with an antiserum prepared against  $\pi$ 2 which neutralised both phages at the same rate ( $K=4,500$ ).

\*10 times and † $1.3 \times 10^6$  times as many donor cells transmitted resistance as in the corresponding established  $R^+$  cultures.

cultures contained a vastly greater proportion of infectable bacteria than the established  $R^+$  cultures, and that the proportion occasionally approached that in cultures carrying  $F$ .

The surface structure, which mediates conjugation by  $R^+$  strains, is determined by  $RTF$ , but has been thought of as distinct from that determined by  $F^+$ . The disappearance of  $F$  function in  $R^+F^+$  bacteria has consequently been attributed to replacement or alteration of the  $F$ -specific surface structure through an epistatic effect of the  $RTF$  suppressing the expression of  $F$  (ref. 13). Our results, on the other hand, suggest that the surface structure determined by  $RTF$  is simply the  $F$ -specific structure expressed in only a few cells, whether the culture is  $R^+F^+$  or  $R^+F^-$ . This view is strengthened by the finding that in cultures which have just become  $R^+$ , and in which repression has evidently not had time to be established, the  $F$ -phage infects a much greater proportion of the cells—almost as many as in an  $R^+$  culture. The unrepressed state of the  $RTF$  in newly-infected cells is only transient<sup>14</sup>, and it is for this reason that plaques are not seen when such cells are plated with  $F$ -specific phage; for by the time the indicator lawn has grown, the normal repressed state of the factor has supervened, and the bacteria are thus phenotypically  $F^-$ .

'pure conditions' was used. There was no growth of the endophyte outside surface-sterilized root-nodule slices incubated for several weeks on agar media of widely differing nutritional composition, including those used for the cultivation of plant tissues *in vitro*. However, when these tissues were crushed in sterile water, a suspension, which although sterile according to the usual microbiological criteria, still produced normal root nodules in sterile alder seedlings growing in test-tubes on a low-nitrogen medium. This would imply that the *Alnus* endophyte is an obligate symbiont and could perhaps be propagated inside alder tissue or root-nodule tissue grown *in vitro*.

Tissue cultures of *Alnus glutinosa* from normal root and root-nodule tissue were started in 1962. Preliminary tests with a number of nutrient media showed that Hildebrandt's<sup>1,2</sup> basal mineral salts-sucrose-agar medium supplemented with coconut milk (150 ml./l.),  $\alpha$ -naphthaleneacetic acid (0.1 mg./l.) and calcium pantothenate (2.5 mg./l.), that is, *O*-medium, gave the best growth *in vitro*. Additional supplements of 'Edamin' (casein hydrolysate), glycine, kinetin, 2,4-dichlorophenoxyacetic acid (2,4-D), etc., did not stimulate this growth.

Small nodules (2–3 mm) from plants grown in test-tubes were surface-sterilized by consecutive application of 96 per cent ethanol for 1 min, 0.5–0.6 per cent sodium hypochlorite and detergent ('Teepol') for 15 min, followed by seven rinsings with sterile water. The nodules were then pre-incubated for several weeks on nutrient agar or *O*-medium for tests of visible 'sterility'. Contamination was usually heavy.

Tissue cultures of root nodules were obtained by placing the surface-sterilized whole nodules or nodule slices on *O*-medium and incubating these in the dark at 27° C. Tissue series exposed to light did not show better growth. The callus tissues produced—usually by bursting of the nodule cortex—were transferred to a new medium of the same composition. Callus tissue of normal roots was obtained from root tips of germinating seeds growing on *O*-medium agar enriched with 2,4-dichlorophenoxyacetic acid (*D*-medium). For maintenance of the root-callus cultures, however, *O*-medium was more favourable.

The tissues were re-transferred to new media about once in 3–4 months, showing the very slow growth rate of alder tissue. After the original isolation of the explants the tissues were transferred 9 times to new media without any reduction in growth. The initial tissues were about 2 mm in diameter and these gave rise to callus tissues of sometimes 25–40 mm in diameter, which represents a volume increase of 2,000–8,000 times the original tissue size. Fig. 1a and b shows a 4-month-old root-nodule callus of *Alnus*.

Most of the root-nodule tissues isolated produced no visible growth in the medium in subsequent transfers. A few, however, did produce actinomyce growth, while the host tissue still continued to propagate (Fig. 2). Sometimes such tissues produced better growth than the apparently 'sterile' tissues. However, ultimately the former tissues produced less growth and finally were overgrown by the actinomyce and died. Since in this way several actinomyce species were isolated, it was doubted that these constituted the true alder endophyte, although one of them may have been the actual endophyte.

To establish whether the *Alnus* endophyte invaded newly-formed host cells in the growing callus tissue, morphological observations of paraffin-wax sections of the tissue were made. In addition the nodule-producing capacity ('virulence') of the tissue was ascertained in inoculation tests with sterile alder seedlings grown in test tubes.

These experiments gave the following results. Host tissue was propagated by transferring a locally fast-developing tissue part to a new medium. This procedure caused a certain selection in cells, which resulted in the

## **In vitro Cultivation of Alder Root-nodule Tissue containing the Endophyte**

ONE of the main problems in non-leguminous nitrogen fixation is the isolation of the endophyte.

In attempts to isolate the symbiont of *Alnus* root nodules, Quispel's method<sup>1</sup> of obtaining the endophyte in

isolation of endophyte-free cells from root-nodule tissue containing the endophyte: apparently host-cell propagation was faster than endophyte transmission. But other transfers did not lose the endophyte. Hyphal structures were observed in the large vacuolated cells typical of callus-tissue cultures, and in the intercellular spaces between the host cells (Fig. 3). However, these tissues when minced and added to sterile alder plants did not

Fig. 1. Callus of root-nodule tissue grown for 4 months *in vitro* in the dark at 27° on C-medium. In some cases the tissue growth is compact and white (a), in other instances more loose and tends to darken with time (b). The differences are, however, not strict; many intermediate growth types are found ( $\times 10$ )

Fig. 2. Root-nodule callus proliferating in spite of actinomyces growth outside the tissue in the agar. Apparently, this actinomyces prefers to grow at lower oxygen tension, as it penetrates the agar forming a broad ring at its surface. ( $\times 10$ )

Fig. 3. Intracellular actinomyces growth in root-nodule callus tissue grown *in vitro*. Only hyphae are observed; note the plant-cell nucleus in the centre of the host cell. Methylene-blue preparation. ( $\times 950$ )

Fig. 4. Sterile alder seedling showing an ineffective root nodule produced by inoculation of root-nodule callus tissue containing the endophyte. Note the pale (yellow) colour of the leaves due to nitrogen deficiency. ( $\times 1.0$ )

produce normal nodulation. In most cases no nodules were formed and within a few months these plants showed severe nitrogen-deficiency symptoms. In a number of plants, however, nodules were produced, but these nodules were ineffective (Fig. 4). Microscopical investigation of the latter nodules showed that they contained the endophyte intracellularly as very fine hyphae, but 'vesicles', or 'bacteria-like cells' typical for normal *Alnus* root nodules, were not observed. It is remarkable that ineffective root nodules occasionally produced by suspensions of normal effective root nodules showed the same internal features.

'Vesicle' formation, therefore, seems to be particularly associated with nitrogen-fixation. As shown by us in electron microscopic work<sup>4</sup>, the 'vesicles' contain many internal cytoplasmic membranes. An analogous observation was made by Dart and Mercer<sup>5</sup> in rhizobial cells of legume nodules. Hence, it may be that these internal cytoplasmic membranes have a special function in nitrogen fixation. The idea that certain membranes play a part in the incorporation of molecular nitrogen is not new. Bergersen<sup>6</sup> has already suggested this in soybean root nodules for the membrane envelopes; however, outside the bacterial cell, enclosing a number of bacteroids.

Root-nodule tissue *in vitro* produced large iso-diametric callus cells, occasionally with clusters of smaller cells due to internal sub-division. Rarely, some tracheal elements with scalariform thickenings of the cell wall were observed. No endophyte differentiation in the callus tissue was found. Only hyphae occurred (Fig. 3); structures like 'vesicles' and 'bacteria-like cells' characteristic for normal root-nodule tissue were entirely lacking.

This investigation shows that its ultimate purpose—the effective nodule-endophyte of *Alnus* in symbiosis with its host tissue *in vitro* culture—has not yet been fully achieved. Alder root-nodule tissue grown *in vitro* and containing its endophyte is a more simple system than that obtained in leguminous symbiosis where, so far, only nodulated isolated roots have been obtained. Direct cultivation of root-nodule tissue containing the endophyte in 'pure' culture will contribute considerably to the study of the physiology of the symbiosis and nitrogen fixation, since substances normally produced by the shoot or root can be excluded and substances, the effects of which are to be tested, can be added to the medium in known amounts.

This communication is a continuation of earlier investigations<sup>1,2</sup> of the physiology of the alder root-nodule symbiotic association.

## RADIOBIOLOGY

### Assimilation and Fermentation Patterns of Osmophilic Yeasts in Sugar Broths at Two Concentrations

Osmophilic yeasts commonly found in intermediate sugar refinery products are strains of *Saccharomyces rouxii* and *S. mellis* with *Torulopsis* spp. which normally grow more slowly under laboratory conditions.

Recent isolates of *S. rouxii*, *T. dothila*, *T. globosa* and *T. apicola* showed differences in reaction where: (1) The ability to ferment various sugars was compared at concentrations of 2 and 10 per cent w/v in yeast extract broth; sterilized in McCartney bottles with Durham tubes at 5 lb./in.<sup>2</sup> for 15 min. Results are summarized in Table 1. (2) The ability to assimilate various sugars was compared at concentrations of 1 and 10 per cent w/v in Difco 'YNB' broth (filter-sterilized and dispensed as 5 ml. vol. into pre-sterilized, capped tubes). Results are summarized in Table 2.

Inocula were taken from fresh slants on osmophilic agar<sup>1</sup>, incubated for 72 h at 30° C, washed and centrifuged in sterile Ringer's solution and, finally, re-suspended in 10 ml. sterile Ringer's solution. One drop of suspension was used per tube.

The variation in reaction does not appear to be due simply to osmotic pressure; as if 9 per cent of the sugar is replaced by an equivalent amount of lactose (negative in every case) the stimulation of the higher concentration was not demonstrated.

Anomalous fermentation patterns were reported last year by J. Santa Maria<sup>2</sup> for *S. rouxii* isolated from sugar cane molasses, but tested at standard sugar concentrations.

All the yeasts were isolated from situations of very high sucrose concentrations. They sub-cultured more readily

Table 1. FERMENTATION TESTS

++ = positive; - = negative; + = weakly positive, ± = variable.

on an osmophilic or semi-osmophilic medium; growth on wort agar or in wort broth is usually very poor. The use of broths with 10 per cent sugar was adopted rather than a higher value because of the low solubility of some sugars such as lactose.

Similar tests on cultures from the Centraalbureau voor Schimmelcultures Delft do not show these variations. The problem arises, therefore, as to whether the incorporation of what are really ecological variations in a test is justified (a parallel case is the use of Koji extract by Onishi<sup>3</sup>). Yeast identification is essentially the 'building-up' of a picture by a number of tests, so ecological modifications must surely be considered. In the case of the osmophilic yeasts, this character may even be lost after growing in media of lower concentrations of sugar for a period<sup>4</sup>.

We consider, therefore, that this group of yeasts should: (a) always be stored in an osmophilic medium which retains these typical properties; (b) biochemical tests should, so far as possible, be adapted to the ecology of the organisms and be carried out in broths containing a minimum of 10 per cent sugar w/v as this produces more consistent results.

## VIROLOGY

### Resistance to Sigma Virus Infection in *Drosophila*

*Drosophila melanogaster* is subject to infection by the sigma virus, either by virus carried in the fly gametes or by extracts from infected flies. Infected flies somehow become 'CO<sub>2</sub>-sensitive' and thereafter are fatally poisoned if subjected to a dose of CO<sub>2</sub>, which is merely anaesthetic to virus-free flies. Plus<sup>1</sup> showed that the time lag (incubation period) between a sigma injection and the onset of CO<sub>2</sub>-sensitivity is a measure of the injected dose, and sigma extracts are now usually titred by using them as inocula and measuring the resultant incubation period in recipient adult flies.

Brun<sup>2</sup> recently reported, for a certain dose, that the incubation time increases in direct proportion to the age of the recipient fly at injection. Further information concerning this age effect is important to the standardization of the assay for sigma virus and to understanding the course of the infection. In addition, the age effect may be related to the poorly understood general phenomenon whereby virus grows slowly or is less pathogenic in aged host tissue, an effect reported for plant<sup>3</sup> and animal<sup>4</sup> viruses.

The influence of imaginal age on the incubation time was tested in the present study by injecting virus extracted from the *Lw Drosophila* strain into reference-strain flies according to procedures previously described<sup>5</sup>. Twenty-five to 30 flies of each age were injected and the average incubation times calculated. The results obtained were similar to Brun's except that, under these conditions, the age-dependence of the incubation time was not linear. As in Brun's study, females required longer incubation times than did males (Fig. 1).

When incubation period is used to estimate inoculum titre, age differences among recipient flies can lead to significant discrepancies. For example, a 17-h difference

in incubation time such as that displayed between newly emerged males and males 12 h old (Fig. 1) leads to a two-fold difference in titre estimate. The standard curve for converting incubation time to inoculum titre has been published elsewhere<sup>4</sup>.

A control experiment was performed in order to ensure that all flies received the same amount of inoculum. There is negligible bleeding following an injection, but because the fly exoskeleton hardens with age, old flies might have accepted less inoculum fluid than young ones. Therefore, at the same time that the flies were injected with virus, an aliquot of five males of each age was injected with randomly labelled leucine-<sup>14</sup>C (0.25  $\mu$ l. of specific activity 0.49  $\mu$ c./ml.). These were squashed immediately on to planchets and then counted in a Nuclear Chicago gas-flow counter.

The average number of counts recovered per individual fly for each age is shown in Fig. 1. The variation in inoculum size as measured by recovered counts is too small and random to account for the observed changes in incubation time and, therefore, indicates that the age effect depends on the *Drosophila* physiology.

A consideration of the sequence of events following the injection of sigma into imagoes suggested that the increase in incubation time might be related to the rate of virus multiplication. It is known that the injection of strain-*La* virus into young imagoes is followed by the multiplication of the virus to a plateau level of  $10^4$ – $10^5$  infectious units per fly. The recipient fly generally becomes CO<sub>2</sub>-sensitive at the time that the virus titre reaches the plateau level<sup>1,2</sup>. The fact that the incubation period was increased in old flies suggested that the virus multiplied more slowly in old flies and reached the plateau value later.

Table 1. TIME REQUIRED FOR INFECTED FLIES TO BECOME CO<sub>2</sub>-SENSITIVE (INCUBATION TIME)

Ageing temperature (°C)	Imaginal age at injection (days $\pm$ 0.063)	Incubation time (days)
25	0.21	7.9
25	13.00	12.1
20	0.17	7.8
20	15.00	12.6

In order to test this hypothesis, virus was injected into young and old flies and the rate of virus multiplication was measured. The procedures used were the same as reported previously<sup>4</sup> except that the reference-strain flies used to assay the virus were 3–7 h old. The results are presented in Table 1 and Fig. 2. The virus doubling time during log phase was indeed increased in old imagoes as compared with young ones. This was true whether the flies

Fig. 2. Growth curves for injected virus.  $X$  is the average number of infectious units/fly. Virus was injected at zero time into flies aged 2 h after eclosion (circles) and into flies aged 13–15 days after eclosion (triangles). Flies had been raised and aged at 25° C (solid symbols) or at 20° C (open symbols).

had been raised and aged at 25° or 20° C. However, the increase in incubation time was greater than expected from the observed lag in virus multiplication. The virus titre plateau in old imagoes was reached about two days later than in young ones, but CO<sub>2</sub>-sensitivity was delayed for two days longer. Therefore, under these conditions, the appearance of CO<sub>2</sub>-sensitivity is dependent on factors in addition to the virus content of the injected fly, and the absence of CO<sub>2</sub>-sensitivity does not preclude a high virus titre in the fly.

### Inhibition of Encephalomyocarditis Virus Replication by Simple Phosphonic and Carboxylic Acids

In view of our recent finding<sup>1</sup> that multiplication of encephalomyocarditis virus (EMC) can be inhibited by non-cytotoxic concentrations of *p*-nitrobenzylphosphonic acid, it appeared worthwhile to investigate the antiviral effect of other phosphonic acids and their carboxylic analogues. It was our hope that the investigation might give some information about the relationship between the chemical structures of the compounds and their antiviral activity, and facilitate the screening of drugs which may be useful in the chemotherapy of viral diseases. In this communication we report the effect of several simple compounds of diverse structure on the replication of EMC virus in the mouse embryo tissue culture.

The EMC virus was maintained by passage in mouse brain and tested in primary mouse embryo (ME) tissue cultures. The commercial carboxylic acids and phosphonic compounds, synthesized by one of us (P. M.) according to the methods indicated in references to Table 1, were used in this work.

\* Sodium salts, pH 7.3-7.4.

<sup>†</sup> Expressed as delay (in days) of degeneration of the cell population infected with virus treated with compound in question in comparison with untreated culture.<sup>‡</sup> Expressed as per cent inhibition of virus yield in the medium measured in plaque-forming units/ml. 20 h after infection.<sup>§</sup> Minimal toxic concentrations of the compounds leading to the microscopically visible degenerative changes of cells during 48 h observation period.

The compounds prepared as 0.1 M solutions of sodium salts, pH 7.3-7.4, were incorporated into the fluid maintenance medium. The medium contained 2 per cent horse serum and 0.5 per cent lactalbumin hydrolysate in Hanks's saline with bicarbonate and antibiotics. The ME cultures (about  $2 \times 10^6$  cells/ml.) were infected with approximately 100 plaque-forming units of virus. The antiviral activity of the compounds was determined by observing the protection of tissue cultures against the cytopathogenic effect (CPE) of the virus and by measurement of the virus yield in the medium 20 and/or 48 h after infection. For the virus titration plaque assays in serological tubes with 1 per cent methylcellulose overlay were used. The details of the methods used were the same as previously described<sup>1</sup>.

The antiviral effects of 27 compounds tested so far are summarized in Table 1.

The results presented indicate that marked antiviral activity (more than 90 per cent inhibition of virus yield and protection against CPE for at least one day) is exhibited by two types of compounds—compounds related to salicylic acid (Nos. 1-3) and certain phosphonic and carboxylic acids with benzyl groups (Nos. 4-9). To our knowledge the antiviral activity of salicylates *in vitro* has not previously been noticed. For this reason their mode of action was investigated more in detail and the results are described in a separate communication<sup>2</sup>.

The significance of the benzyl grouping associated with different structures for virus inhibition emerges from the results of several investigators. Tamm *et al.*<sup>12</sup>, who have examined the inhibition of virus replication by numerous derivatives of benzimidazole, suggested that hydroxybenzyl grouping at position 2 in the imidazole ring was of importance for the selective antiviral activity of 2-( $\alpha$ -hydroxybenzyl)-benzimidazole (HBB). O'Sullivan *et al.*<sup>13</sup> synthesized several substituted HBB derivatives with high inhibitory action on poliovirus multiplication and concluded that the 1-benzyl derivative of HBB is among the most active compounds. Loddo and Gessa<sup>17</sup> have recently reported that benthanidine and *o*-chlorobenthanidine, which are benzyl derivatives of guanidine, have a considerable inhibitory action on polio and vaccinia virus growth although presumably exerting their effects through a different mechanism from that of guanidine.

The work recorded here has revealed that certain simple compounds with the benzyl grouping attached to electro-negative, electrophilic structures (carboxylic or phosphonic) also suppress the replication of EMC virus, whereas the compounds with the phenyl,  $\beta$ -phenylethyl and some other groups show little, if any, virus inhibitory action. Moreover, the dibenzyl structure was found to be far more active than mono-benzyl structure. It was also observed that the nitro group increased, whereas the amino group reduced, the antiviral effect of the compounds.

Even the most active of the compounds tested so far require a rather high concentration of  $2 \times 10^{-3}$  M/l. for activity and their effect diminishes rapidly at lower concentrations. On the other side, the increase of concentration from  $2 \times 10^{-3}$  to  $5 \times 10^{-3}$  was not followed by significant increase of percentage inhibition of virus yield. In case of phosphonic acids and of salicylic acid and its derivatives the high concentration necessary is counterbalanced, however, by low toxicity. For this reason the active doses were always several times lower than the toxic doses. Among the highly active compounds only *p*-nitrophenylacetic acid was found to be cytotoxic at a concentration of  $2.5 \times 10^{-3}$  M and slightly inhibited oxygen consumption and lactic acid production by mouse embryo tissue. It was, however, interesting to note that its phosphonic analogue, *p*-nitrobenzylphosphonic acid, conferred to cells rather high protection against virus infection although it was several times less toxic and did not significantly affect the tissue respiration.

In preliminary experiments *p*-nitrophenylacetic acid and dibenzylphosphonic acid gave distinct protection of

mice infected with lethal doses of EMC virus. The *in vivo* activity of *p*-nitrobenzylphosphonic acid was described previously<sup>1</sup>.

We thank Dr. A. C. Allison and Prof. Z. Skurka for their advice.

## GENETICS

### Genetic Recombination with Ethyl-methanesulphonate-Induced Waxy Mutants in Maize

INTRACISTRON mapping in maize has been demonstrated by Nelson<sup>1,2</sup> with a technique based on differential staining reactions of starch in pollen of different genotypes. Those with the *waxy* (*wx*) locus stain reddish brown in iodine-potassium iodide solutions; whereas *non-waxy* (*Wx*) pollen stains dark blue. Therefore, in *waxy* plants genetic recombination or back-mutation at this locus is manifested by the appearance of dark blue staining pollen. The technique has a distinct advantage in genetic investigations with higher plants in that large populations of hundreds of thousands of genotypes (pollen grains) can be scored with ease.

As part of a programme in progress here on chemical mutagenesis in higher plants, the *wx* locus in maize is being used as experimental material and ethyl-methanesulphonate (EMS) as one of the chemical mutagens<sup>3</sup>. This communication is a preliminary report of results obtained with EMS on the induction of *wx* mutations at independent sites and the ordering of these sites within the locus. So far, nearly 50 *wx* mutations have been induced in the programme. Although each appeared independently, some of the sites may be identical, and this will be investigated in subsequent research. A number of mutants other than *waxy* have also been produced with EMS (ref. 3). Results with these, together with the data on *waxy* mutations, are providing preliminary evidence that EMS produces 'point' mutations in maize.

Results are reported here for four of the EMS-induced *waxy* mutants. These were obtained from seed treatments. Disinfected seeds were first soaked in deionized water at 27° C and bubbled continuously with oxygen for 24 h. They were then soaked in 0.05 M or 0.025 M aqueous solutions of EMS for either 2 or 3 days at 3° C. The rationale for this

Table 1. GENETIC RECOMBINATION BETWEEN A *waxy* TESTER AND *wx* SITES INDUCED WITH ETHYL-METHANE SULPHONATE IN MAIZE

Mutant	Seed treatment conditions			Recombination data	
	Molarity of EMS	Days at 3° C	24-h post-treatment (° C)	Ret. No. microspores ( $\times 10^4$ )	$\bar{X}$ No. $Wx \times 10^{-3} \times 2$
BNL-85	0.05	2	27	85	25.6
BNL-87	0.025	3	3	376	44.2
BNL-88	0.025	3	3	409	76.2
BNL-88	0.025	3	18	603	86.0

treatment was to ensure thorough penetration without chemical disintegration of the mutagen. This was followed by post-incubation in water at different temperatures (Table 1).

The plants grown from treated seeds were crossed to a tester stock that was recessive at the *waxy* locus. The occurrence of *waxy* kernels in the  $F_1$  indicated a mutation. The presence of  $Wx$  pollen in the  $F_1$  plants, in excess of back-mutation frequency, was evidence of recombination between the tester and mutant *wx* site.

Recombination results on the four sites are shown in Table 1. These were selected for reporting in this preliminary article because closely comparable results were obtained by two observers (R. B. and E. A.), working completely independently of each other. The figures shown in Table 1 are averages computed from the two sources of data. The number of  $Wx$  grains has been multiplied by two to be comparable with other recombination maps. The mutant sites are arranged in Table 1 in order of increasing amount of recombination with the tester.

In so far as the  $Wx$  pollen in  $F_1$  plants heteroallelic for tester and mutant *wx* sites arises from genetic recombination, this result, in itself, is an indication that the mutant sites are positioned differently from the tester site in the *wx* locus. The results in Table 1 have not been corrected for the spontaneous back-mutation rate. Evidence from other research<sup>4</sup> with standard *waxy* sites shows that back-mutation rates range from 0.60 to  $2.42 \times 10^{-4}$ , which is about equivalent to a map distance of 0.0012–0.0048. The range of recombination of the mutants reported was from 0.0256 to 0.086. Therefore, the recombination figures shown in Table 1 are considerably in excess of a back-mutation rate from other work. Furthermore, the results presented here indicate a back-mutation frequency of zero for the homoallelic tester used in this research.

Mapping by the described procedures gives the relative recombination distances from one site. However, if a map is constructed by this method it may not give the true spatial relationships since at present all mutants are mapped to one side of the tester site.

Future mapping will be done by first obtaining stocks which are homoallelic for the induced site. These will then be intercrossed in all possible combinations so that the actual recombination distances among induced sites can be determined, rather than only the distance from the tester site. This conventional mapping method should show whether induced sites are distal or proximal to the tester site and, hence, their true spatial relationships. Furthermore, by following such a procedure insight should be gained on whether EMS-induced sites are 'point' mutations or minor deletions. The *ad hoc* mapping procedure used here is not capable of distinguishing small deletions from 'point' mutations since recombination would be expected in both. However, by the conventional mapping procedure, minor deletions should be distinguishable by non-additivity of recombination distances when all the combinations of a diallel system of crosses are tested. In the course of the analysis evidence for major chromosomal damage should also be detectable.

In summary, the evidence for intracistron recombination reported here indicates that EMS induces independent mutations at sites within the *waxy* locus in maize. The occurrence of recombination between mutant and tester *wx* sites is further indication that 'point' mutations, or at least minor deletions, have been induced by this mutagen.

We thank Miss Elizabeth Hamill for her assistance. This work was carried out under the auspices of the U.S. Atomic Energy Commission.

## PSYCHOLOGY

### Inappropriate Constancy Explanation of Spatial Distortions

THE perception of two- and three-dimensional space has for long been one of the central issues in the experimental study of sensory and perceptual processes. An aspect of this problem is the apparent distortions of shape, size and direction which occur when the elements of a stimulus pattern (lines, angles, forms, etc.) are juxtaposed in certain spatial relationships. Such spatial illusions, which can be defined as discrepancies between the judged and true physical properties of the stimulus, have not yet been explained satisfactorily. It is clear, however, that their explanation would constitute a considerable advance in our understanding of the perceptual processes involved in space perception.

Interest in illusory patterns has been revived recently by a further attempt at their explanation by Gregory<sup>1-3</sup>, who has extended and tested a theory originally proposed by Tausch<sup>4</sup>. Although this theory has the virtue of simplicity in addition to that of interpreting illusory phenomena in the context of the established principle of perceptual constancy, it can be seriously questioned on several grounds. Some criticism has already been raised by Brown and Housiadas<sup>5</sup>.

Gregory argues that the classical spatial illusions are two-dimensional projections of three-dimensional objects such that those elements normally further away in three-dimensional space appear larger. The principle of 'misapplied' or 'inappropriate' constancy can be illustrated in Hering's illusion shown in Fig. 1. The two vertical lines in this pattern are parallel. The radiating lines give a perspective effect; the centre of the pattern represents a point more distant than points around the margin. Since the distance between the two vertical lines is constant throughout, the visual sub-tense is also constant. But the central region of the pattern contains information for greater distance than the margin. In order to subtend the same visual angle, therefore, the separation between the parallels in the centre must be perceived as greater than at the ends, hence the outward bowing effect of the parallels. The principle of inappropriate constancy is also illustrated in the variants of Ponzo's illusion from Teuber<sup>6</sup> also shown in Fig. 1. In summary, information or cues for greater or less distance contained in the background pattern will determine the apparent size of elements in a two-dimensional display.

The principle involved is precisely that invoked by Ptolemy to explain the Moon illusion, that is, the greater apparent size of the Moon at the horizon as compared with its size at zenith. In each location the Moon subtends much the same visual angle, but the horizon is judged further than the vertical distance. Thus the Moon must be judged larger at the horizon. This apparent distance theory of the Moon illusion has been strongly supported by data from a series of recent experiments<sup>7</sup>.

A first point of criticism which has already been raised<sup>8</sup> concerns the occurrence of spatial illusions in the tactile modality. It has for long been known that spatial illusions similar to those in vision occur when the same

line patterns are impressed on the skin. A number of early investigators and, more recently, Reeves<sup>8</sup> and Rudel and Teuber<sup>9</sup> have demonstrated the occurrence of numerous spatial illusions for both active and passive touch. Further, Reeves has ruled out a dependence of these tactile illusions on vision by observing their occurrence among subjects blind from birth.

Since the touch receptors of the skin constitute a 'contact' sense which is not adapted for three-dimensional spatial discrimination, it is difficult to argue that distance information in the surrounding pattern determines the illusory effect through inappropriate constancy. Both the visual and tactile sense organs are constituted of a spatially extended receptor mosaic and the occurrence of similar illusory effects for each modality strongly suggests similar processes. A parsimonious theory would be expected to account for each. This criticism is reinforced by the recent finding that the receptor mosaics of both the skin and retina contain mechanisms which enhance borders and edges to give the Mach effect<sup>10</sup>.

A second point involves numerous variants of the Zöllner illusion. In Fig. 2A are shown the Zöllner, Wundt and Orbison illusions, all of which derive from and are complex versions of the intersection of one line with another as shown in Fig. 2B. If the line to be judged is vertical its apparent slant in the opposite direction to the slant of the intersecting line is a function of the angle of intersect as shown in Fig. 2C. The illusory effect is minimal at angles of approximately 22° and 67°. Thus, if line patterns are of variable angle and direction, as in the three patterns in Fig. 2A, the illusory effect will vary

Fig. 1. The Hering illusion (left) and two versions of the Ponzo illusion (right) demonstrating the misapplied constancy principle

Fig. 2. A, Illusions deriving from the intersection of two lines; B, the simple case, C, variation in the direction of an illusion of slant as a function of the angle of intersection

Fig. 3. Illusion of slant as a function of angles of intersection of 22.5° (upper) and 67.5° (lower)

according to the particular locus of the verticals on the background. Although the multilined backgrounds of the patterns in Fig. 2A contain perspective information for distance, the same can scarcely be said of the simpler and more basic pattern of Fig. 2B. That is, the well-known illusions of Zöllner, Wundt and Orbison are each complex versions of the relatively simple case shown in Fig. 2B in which it is extremely difficult to conceive of an apparent distance determinant.

A further point arises out of this variation in the magnitude of 'directional' illusions as a function of intersect angle as shown in Fig. 2C. At intersect angles of about 22° the two parallels appear closer in the lower part of the pattern and at angles of about 67° farther apart. But the distance information from the background perspective is the same in each case. This difficulty for the constancy interpretation is illustrated in Fig. 3. It can be noted also that a number of directional and size illusions change, often exhibiting the reverse effect, when the background pattern is systematically varied with respect to certain properties.

The Müller-Lyer illusion is an example of an illusion which can be seen in a variety of patterns. The 'dumbbell' illusion<sup>11</sup> shown in Fig. 4 is one such variant. The attached circles have the effect of lengthening or shortening the horizontal lines. Now, although the angles attached to the lines in the classical Müller-Lyer figure can be thought of as containing perspective information for distance, the same can scarcely be said of the circles in Fig. 4, all of which are the same diameter and vary only in the distance apart of their centres. To attribute distance information to equal circles would seem to be stretching the misapplied constancy hypothesis to breaking point, especially as the two circles suggesting greater distance (those closer together) produce an illusion of being shorter.

Fig. 4. The 'dumb-bell' illusion. The horizontal lines are equal in length

Gregory has also attempted to explain spatial after-effects in terms of inappropriate constancy. These effects occur in judgments of visual patterns following prolonged stimulation by another. To attribute these effects to the same processes as those responsible for spatial illusions fails to take into account that in using the same patterns to generate an illusion and an after-effect the directions of distortion are frequently opposite. This opposition between illusion and spatial after-effect is illustrated in Fig. 5. The surrounded dotted circle appears larger than the objectively equal but non-surrounded circle. If, however, the surrounding circle is fixated for a minute and then the dotted circle compared, the circle falling within the hitherto stimulated region appears smaller. In any event, it has now been shown that there is no necessary relation between spatial illusions and spatial after-effects<sup>1</sup>.

Fig. 5. Figures for showing the opposition between illusion and after-effect

There now seems to be little doubt that certain illusory phenomena derive from an apparent distance-apparent size invariance. The Moon illusion is one such case<sup>2</sup> and is probably a special case of Emmert's law as demonstrated by King and Gruber<sup>3</sup>. The argument that the classical spatial illusions and spatial after-effects derive from an essentially similar size-distance invariance is, to say the least, questionable in view of the contrary evidence presented here. In point of fact there is evidence which strongly suggests that the apparent distortions of illusory figures derive from neural interactions between the processes induced by the judged and background elements of the pattern<sup>4</sup>. If this explanation can be sustained then apparent distance would be a consequence, not a cause, of spatial distortions.

PROF. DAY omits the major feature of my theory. The omission is evident in his reference to the Moon illusion. What is interesting about the Moon illusion is that its

apparent size is not a simple function of its apparent distance. On the horizon it appears large and near. Ptolemy was not correct in attributing its apparent size simply to its apparent distance, and the effect is not a straightforward example of Emmert's law. For this and other reasons I suggested that there is more to constancy than apparent distance: that constancy can be set directly by depth cues which are not always appropriate. Prof. Day disregards what I have called "primary constancy scaling" without which I believe we cannot hope to develop a consistent theory of these distortions in terms of depth perception.

The reported illusions in the tactile modality are certainly interesting, but should not be regarded as a straightforward "criticism", or objection, to a theory of the visual illusions in terms of depth. It seems much more to the point to discover more about these tactile illusions—to discover how they are related to the visual ones. The fact is we know very little about them. Further, it is not at all clear why this "criticism" is reinforced by the fact that borders and edges are neurally enhanced in both touch and vision. Why should the Mach effect be relevant to distortion illusions?

The discussion of the Zöllner, Wundt and Orbison illusions is not aimed at my theory, because the essential point of primary scaling is omitted. In each case the depth features of these figures can be related, by isolating the features and measuring the perceived depth of each, with the technique described briefly in my reply to Brown and Housiadas<sup>5</sup>.

Regarding figural after-effects: the notion that they may be due to constancy scaling taking some time to recover after prolonged fixation was put forward as a suggestion which seems worth following up. It is probably consistent with the known facts; but again it must be discussed in terms of 'primary' scaling. This is set by local depth features which may be opposed by other features or countermanded by the texture of the background. It is not synonymous with apparent distance except in the simplest cases, but in all cases it is possible to isolate the depth features and measure the primary constancy. This can then be directly related to the distortion of visual space in the X- and Y-co-ordinates.

## SOIL SCIENCE

### Tracer Technique used in Examination of Activity of Roots of Grass Swards

THE interpretation of measurements of the uptake by plants of tracer isotopes from the soil is complicated by at least three factors. First, exchange takes place between the added labelled ions and the isotope ions present in the soil; the rate of this exchange has been shown to be affected by many factors<sup>1,2</sup>. Secondly, continuous exchange occurs between the nutrient ions in the roots and those in the soil<sup>3-5</sup>. The factors controlling this exchange are unknown. Thirdly, there is the possibility of damage to plant tissues, resulting from accumulation of the tracer. Although a number of experiments have shown no appreciable effects of radiation in terms of yield of dry matter<sup>6-12</sup> and uptake<sup>6,13</sup>, the question of radiation damage to plant tissues in long-term uptake experiments remains unsettled. Critical studies<sup>13,14</sup> have shown that even very low doses of radiation may produce some physiological changes in plant cells.

The problems of isotopic exchange make it impossible to compare quantitatively the amounts of tracer found in plants, at different sampling dates, in experiments in

which labelled isotopes have been placed in the soil on a single occasion. Radiation damage to absorbing cells can also invalidate such results, so that this method cannot be used to follow changes with time in the uptake of particular ions by the roots. These difficulties are minimized if uptake can be measured after a few hours only.

Changes in uptake during a given time period can be examined by repeated placement of a standard dose of tracer and measurements of the uptake by the plants over a fixed short period. Plants to which tracer has not been previously supplied are used on each occasion. This technique was considered for use in an examination of rooting differences in field swards subjected to progressively differing soil moisture conditions. Two aspects only of the technique are presented here, namely, the time interval required following placement of  $^{32}\text{P}$ , for measurable amounts to appear in the herbage, and the effect of soil moisture content, at the time of placement, on the distribution of  $^{32}\text{P}$  in the soil. In both cases, Italian ryegrass (*Lolium multiflorum*) growing on a coarse sandy loam was used.

In examining the first question,  $^{32}\text{P}$  was placed at different depths on July 19, 1963, when the sward had been cut once in the spring and the soil had received no fertilizer since the preceding barley crop. A  $\frac{1}{4}$ -in. steel rod was driven into the soil and a polythene tube liner was inserted into the hole to reach about  $\frac{1}{2}$  in. from the bottom. The  $^{32}\text{P}$  solution (25  $\mu\text{C}$ ,  $^{32}\text{P}$  carrier free as orthophosphate, in 0.4 ml. water) was then placed at the bottom of the hole with a surgical syringe fitted with a fine delivery tube. The parts of the plants above ground were sampled at intervals ranging from 6 to 72 h after placement of the tracer. Each sample consisted of the grass on a roughly circular area (4 in. diameter), cut at ground level around a single placement point. The dried (100° C, 12 hours) plant samples were ashed by ignition (450° C), and taken up in 2 N nitric acid after the method described by McAuliffe<sup>7</sup>; a sample of the solution was counted in a Geiger-Müller solution counting tube.

Sufficient  $^{32}\text{P}$  was taken up in the first 6 h after placement, even from a depth of 6 in., to allow satisfactory measurement of radioactivity (Table 1). Variability was high, but was considerably reduced in subsequent work by multiple placement.

The effect of soil moisture content, at the time of placement, on the distribution of the tracer was examined on a similar sward. In one treatment (dry), the 0-2 in. soil horizon contained 5.1 per cent moisture (moisture content at 15 atmospheres  $\approx$  3 per cent). During the 6 h before the tracer was placed, the second treatment (wetted) was watered to field capacity ( $\approx$  13 per cent moisture). On each plot,  $^{32}\text{P}$  (25  $\mu\text{C}$ , in 0.4 ml. water) was placed at a depth of 1 in. at two points spaced 6 in. apart. In order to deliver the tracer in the soil at as uniform a rate as possible, a standard time of 15 sec was taken to complete placement at each point. Each dry matter sample for radio-assay was a strip of grass 3 in. wide out at ground level between the two points of placement. Sampling was done exactly 4 h after the tracer had been applied. Identical experiments were carried out on two dates—August 31 and September 5, 1963, each being repeated five times.

Autoradiographs of vertical cross-sections from duplicate soil monoliths show that  $^{32}\text{P}$  became distributed over

Fig. 1. Autoradiographs of soil monolith vertical cross-sections, showing the distribution of  $^{32}\text{P}$  (25  $\mu\text{C}$ , in 0.4 c.c. water) 4 h after placement. A, Soil at field capacity ( $\approx$  13 per cent moisture) at time of placement; B, Soil containing 5.1 per cent moisture at time of placement.

a much greater vertical range, up the sides of the hole, in the wetter soil (Fig. 1). Moisture content of the soil had therefore a very pronounced effect on the distribution of the  $^{32}\text{P}$  tracer solution. The effect of the treatments on the uptake of  $^{32}\text{P}$  by the grass is shown in Table 2.

The result of wetting immediately before placement is a very large increase in tracer uptake. This uptake is greater than the increased soil distribution of the tracer would suggest. However, the amount of root material under a sward declines rapidly with increasing depth from the surface and, as Fig. 1 shows, the effect of wetting before placement is to raise the upper margin of tracer-affected soil. It is not surprising that uptake values differed so greatly at the two levels of moisture content; widely differing amounts of root surface must have been exposed to the tracer in the two treatments. In using a tracer-solution placement technique to compare uptakes by plants which have been grown under different moisture regimes, it is therefore necessary to standardize the moisture content of the soil under the different treatments before the tracer is placed; in the field this can be done only by bringing the soil to field capacity on each sampling occasion.

Increasing the moisture content of the soil on plots which have previously been submitted to progressive drying may enhance tracer uptake, because of a probable increase in the diffusion of ions to absorbing cells, and because of a possible increase, even in the few hours following re-wetting, in the capacity of the roots for ion uptake. However, if the soil moisture condition in the preceding period has had pronounced effects on the amount and distribution of absorbing roots or on the rate at which the root surfaces take up the ion concerned, these will be reflected in the uptake recorded. Thus the use of this technique in the field should demonstrate relative differences in ion uptake of root systems at particular depths and as affected by different moisture regimes.

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

**RESEARCH ASSISTANT** (biologist or veterinarian) in the DEPARTMENT OF VETERINARY ANATOMY, for locational studies—The Registrar, The University of Liverpool, Liverpool 3, quoting Ref. OV/228/N (August 27).

**SENIOR TECHNICIAN** (experienced in biological techniques, and an interest and ability in laboratory administration); and **TECHNICIAN (2)** (experienced in biological techniques) in the DEPARTMENT OF ZOOLOGY—The Deputy Secretary, The University, Southampton (August 27).

**LECTURER IN HUMAN GENETICS**—The Registrar, The University, Newcastle upon Tyne, 2 (August 28).

**RESEARCH ASSISTANT** (with a first degree in chemistry, biochemistry or zoology) in BIOCHEMISTRY, to join a research group carrying out research into the biochemical and nutritional properties of food after processing—The Deputy Secretary, The University, Southampton (August 30).

**RESEARCH FELLOW** (with experience in computer programming and data processing) in MEDICAL DATA PROCESSING in the SUB-DEPARTMENT OF NUMERICAL ANALYSIS—The Registrar, The University, Liverpool 3, quoting Ref. OV/237 (August 30).

**ASSISTANT STATISTICIAN** for a diverse range of work at the Authority's statistical unit at Letchworth, Hertfordshire—The Establishment Officer, Pig Industry Development Authority, 15 Ridgmount Street, London, W.C.1 (August 31).

**EXPERIMENTAL OFFICER** (young graduate interested in the design and construction of electronics and electro-acoustic equipment) in the DEPARTMENT OF AUDIOLOGY AND EDUCATION OF THE DEAF—The Registrar, The University, Manchester, 13, quoting Ref. 161/65/Wa (August 31).

**STATISTICIAN** (Assistant Lecturer/Lecturer or Experimental Officer level) in the DEPARTMENT OF PREVENTIVE MEDICINE AND PUBLIC HEALTH—The Registrar, University of Sheffield, Sheffield (August 31).

**TECHNICIAN** for a research laboratory, to assist in low temperature experiments and also to assume responsibility for the organization of teaching experiments—The Registrar, University of Warwick, Coventry, quoting Ref. 2/65 (August 31).

**PART-TIME ASSISTANT LECTURER or DEMONSTRATOR in ANATOMY**—The Registrar, The University, Manchester 13, quoting Ref. 166/65 (September 3).

**SENIOR LECTURERS (2)**, and **LECTURERS/ASSISTANT LECTURERS** (with at least a good honours degree with suitable teaching and research experience) in the DEPARTMENT OF MATHEMATICS, University of Malaya—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Kuala Lumpur and London, September 6).

**TECHNICAL OFFICER** (preferably with qualifications in science or engineering) in the DEPARTMENT OF PHYSICS, to assist the Departmental Secretary in the administration of laboratories—Dr. P. Matland, Secretary, Faculty Board of Physics and Chemistry, Chemical Laboratory, Lensfield Road, Cambridge (September 8).

**RESEARCH SCIENTIST or SENIOR RESEARCH SCIENTIST** (Organic Chemist) (with a Ph.D. degree in chemistry, or with postgraduate research experience of equivalent standard and duration, supported by satisfactory evidence of research ability) in the DIVISION OF ORGANIC CHEMISTRY, Commonwealth Scientific and Industrial Research Organization, Chemical Research Laboratories, Fishermen's Bend, Melbourne, Victoria, Australia, to participate in chemical studies of biologically active plant metabolites—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 606/66 (September 11).

**ASSISTANT LECTURER in ZOOLOGY**—The Registrar, The University, Manchester, 13, quoting Ref. 165/65 (September 15).

**DEMONSTRATOR/SENIOR DEMONSTRATOR in the DEPARTMENT OF ORGANIC CHEMISTRY**—The Registrar, The University, Newcastle upon Tyne, 2 (September 15).

**LECTURER or ASSISTANT LECTURER in the SCHOOL OF PHARMACY, University of Singapore**—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (September 16).

**NUFFIELD POST-DOCTORAL FELLOW** (with experience in metabolic aspects of cell metabolism) in BIOCHEMISTRY in the DEPARTMENT OF AGRICULTURAL BIOCHEMISTRY, Waite Agricultural Research Institute, to assist in a programme of work on the biochemistry of nitro fixation in bacteria—The Registrar, The University of Adelaide, Adelaide, South Australia (September 17).

**PROFESSOR, and a SENIOR LECTURER or LECTURER in STATISTICS** at the University of Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (September 18).

**LECTURER in HISTORICAL or MECHANICAL ENGINEERING** at Fourah Bay College, The University College of Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (September 20).

**LECTURER** (with an honours degree in chemistry and preferably the degree of Doctor of Philosophy) in INORGANIC CHEMISTRY at the University College of Townsville (University of Queensland), Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (September 24).

**LECTURER in the DEPARTMENT OF ORGANIC CHEMISTRY, University of New South Wales, Australia**—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 30).

**LECTURER** (qualified in the field of palaeontology) in GEOLOGY at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, September 30).

**SENIOR CHAIR in ZOOLOGY** at the University of Canterbury, Christchurch, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, September 30).

**SENIOR LECTURER and a LECTURER in BIOCHEMISTRY** at the University of Adelaide, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia, September 30).

**SENIOR LECTURER** (with a degree in science or engineering, preferably a doctorate, experience in the maintenance and operation of electron microscopes, and a wide knowledge of electron microscopy techniques, including application to biological, mineral and metallurgical materials) in ELECTRON MICROSCOPY at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (October 1).

**LECTURER or SENIOR LECTURER** (medical graduate with postgraduate experience in pathology) in the DEPARTMENT OF PATHOLOGY, University of Otago, Dunedin, New Zealand—The Professor of Pathology, University of Otago Medical School, P.O. Box 918, Dunedin, New Zealand; or The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, November 30).

**AGRICULTURAL OFFICERS** (nationals of the United Kingdom or the Republic of Ireland, with a degree in agriculture or natural science, plus at least two years experience in tropical agriculture) in Sarawak, for the administration of an Agricultural Division, comprehensive advisory and supervisory duties, and supervision of experimental stations and staff training—The Appointments Officer, Ministry of Overseas Development, Room 301, Bland House, Stag Place, London, S.W.1, quoting Ref. 219/185/04.

**ANIMAL TECHNICIAN** (male, with at least five years experience) in the BIOCHEMICAL LABORATORY, to take charge of department concerned mainly with nutritional research on small animals—The Director of Research, Cereals Research Station, Old London Road, St. Albans, Herts.

**ASSISTANT LECTURER in CHEMICAL METALLURGY**—Prof. F. D. Richardson, Department of Metallurgy, Imperial College, London, S.W.7.

**ASSISTANT LECTURER** (interested in a research career) in the DEPARTMENT OF HUMAN BIOLOGY AND ANATOMY, for duties which will include the teaching of gross anatomy—Prof. B. Barer, Department of Human Biology and Anatomy, The University, Sheffield, 10.

**BACTERIOLOGIST** (with a first or good second-class honours degree, or equivalent qualification, in a biological science, and research experience in bacteriology) in the ISOTOPE RESEARCH DIVISION'S MICROBIOLOGY SECTION, Vantage Research Laboratory, A.M.R.B., to study the lethal effect of radiation on bacteria, particularly in relation to the influence of various environmental factors—Personnel Department (A. 5116/84), United Kingdom Atomic Energy Authority, Atomic Energy Research Establishment, Harwell, Didcot, Berkshire.

**BIOCHEMIST** (Basic Grade) to work with and under the direction of a Chemical Pathologist and the Group Biochemist—The Director of Pathology, Paddington General Hospital, Harrow Road, London, W.9.

**BIOCHEMIST in the MEDICAL UNIT** as research assistant on the isolation of peptide hormones—Prof. J. Anderson, Medical Unit, King's College Hospital, Denmark Hill, London, S.E.5.

**BIOCHEMIST** (probationary or basic grade)—The Group Secretary, Napsbury Hospital, near St. Albans, Herts.

**CHEMIST, PHYSICIST or BIOCHEMIST** (graduate) for work on the application of gas chromatography for the determination of steroid progesterone—Dr. A. B. Kellie, Courtauld Institute of Biochemistry, Middlesex Hospital Medical School, London, W.1.

**COMPUTER PROGRAMMER** (recent graduate with appropriate qualifications or experience in computing techniques) for a research group in astrophysics at the Cambridge University Observatories—The Director, Observatories, Madingley Road, Cambridge.

**ENTOMOLOGIST** (male, normally national of the United Kingdom or the Republic of Ireland, with an honours degree in entomology, biology or zoology with an emphasis on entomology) in Tanzania, to carry out major surveys of tsetse infested country, to plan and estimate the cost of control measures and to finally evaluate the results—The Appointments Officer, Ministry of Overseas Development, Room 301, Bland House, Stag Place, London, S.W.1, quoting Ref. RO 217/178/07.

**EXPERIMENTAL OFFICER or SENIOR EXPERIMENTAL OFFICER** (man with an agricultural degree or N.D.B.) to conduct field experiments in new techniques in farm mechanization—The Secretary, National Institute of Agricultural Engineering, Scottish Station, Bush Estate, Pentonik, Midlothian.

**FRESHWATER RESEARCH OFFICER** (national of the United Kingdom or the Republic of Ireland, with an honours degree in natural science, with at least two years postgraduate research experience in freshwater biology, fisheries research or limnology) with the East African Common Services Organization, to investigate various problems of the freshwater fisheries in East Africa, commencing with those encountered in Lake Victoria—The Appointments Officer, Ministry of Overseas Development, Room 301, Bland House, Stag Place, London, S.W.1, quoting Ref. RO 236/214/03.

**FOREST ENTOMOLOGIST** (under 45, national of the United Kingdom or the Republic of Ireland, with a degree in zoology or entomology, with postgraduate experience in some aspect of tropical forest entomology) with the East African Common Services Organization, to work under the general direction of the Head of the Forest Entomology Division and the Director of the East African Agriculture and Forestry Research Organization on extensive field studies of tree-bored and defoliators, to assist with the East African Forest Insect Survey and with the expansion and upkeep of the I.A.A.F.R.O. reference collection of forest insects—The Appointments Officer, Room 301, Ministry of Overseas Development, Bland House, Stag Place, London, S.W.1, quoting Ref. RO 224/214/02.

**HIGHER TECHNICAL ASSISTANT** (with wide experience of laboratory techniques with special reference to physiological problems) in the PHYSIOLOGY LABORATORY—The Secretary, School of Agriculture, University of Cambridge, Downing Street, Cambridge.

**LABORATORY TECHNICIAN** for routine steroid hormone estimations—The Assistant Secretary, University College Hospital, Gower Street, London, W.C.1.

**LECTURER in PSYCHIATRY** at the University of the West Indies, Kingston, Jamaica—The Secretary, Senate Committee on Higher Education Overseas, University of London, Senate House, London, W.C.1.

**PHYSICIST FOR THE RADIOTHERAPY SECTION OF THE HOSPITAL'S PHYSICS DEPARTMENT**—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, quoting Ref. No. A80/468.

**PHYSICISTS** (Auroral Spectroscopists) at the Churchill Research Range, Fort Churchill, Manitoba, Canada, for a programme of research in auroral spectroscopy—The Employment Officer, National Research Council of Canada, Ottawa, 7, Canada, quoting Ref. ORH-1.

**RESEARCH ASSISTANT** (graduate) in the DEPARTMENT OF MICROBIOLOGY, for studies of invasiveness of cancer cells—Prof. H. Smith, The University, Birmingham, 16.

**RESEARCH ASSISTANT** (graduate or G.R.I.O.) in the DEPARTMENT OF CHEMISTRY, to work on the far infrared spectra of compounds—Head of the Department of Chemistry, Northampton College of Advanced Technology, St. John Street, London, E.C.1, quoting Ref. O/N.

**RESEARCH ASSISTANT** (honours graduate in biological science) in the DEPARTMENT OF EXPERIMENTAL PATHOLOGY AND CANCER RESEARCH, for an investigation of biological aspects of carcinogenesis—Dr. J. O. Laws, Department of Experimental Pathology and Cancer Research, School of Medicine, The University, Leeds, 2.

**RESEARCH ASSISTANT in MYCOLOGY**—The Secretary, Wright-Fleming Institute of Microbiology, St. Mary's Hospital Medical School, Paddington, London, W.2.

**RESEARCH ASSISTANT** (with a B.Sc. in microbiology or similar qualification) for the HOSPITAL INFECTION UNIT in the DEPARTMENT OF BACTERIOLOGY—Clark to the Governor, St. Bartholomew's Hospital, London, E.C.1, quoting Project No. 109/2, reference No. ASO/465.

**RESEARCH ASSISTANT** (with a degree in chemistry and some experience in a field of polymer research) in POLYMER CHEMISTRY—The Registrar, Ref. 118Y/X, Bradford Institute of Technology, Bradford, 7.

**RESEARCH BIOCHEMIST** (under 35, biochemist or biologist with a Ph.D.) for biochemical and immunochemical research on lipocarbohydrates—The Personnel Director, Evanston Hospital Association, 2650 Ridge Avenue, Evanston, Illinois, U.S.A.

**RESEARCH SCIENTISTS** (graduates or equivalent in chemistry, physics or wood science) for investigations into (a) gluing of timber and composite materials; and (b) wood finishes: paints, varnishes, stains, water repellents, etc.—The Secretary, Timber Research and Development Association, 81, John's Road, Tysons Green, High Wycombe, Bucks.

**SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER** (honorary graduate in bacteriology or microbiology) in the BACTERIOLOGY DEPARTMENT, for work concerned with the role of micro-organisms in the nutrition of the ruminant—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, Berkshire, quoting Ref. 65/8.

**SENIOR OR CHIEF TECHNICIAN** (with a good knowledge of workshop practice and some experience of vacuum techniques and electronics) to work with a research group on atomic beam research projects, concerned with gas scattering, optical and electron excitation and radio-frequency resonance—The Laboratory Superintendent, Physics Laboratory, University of Sussex, Falmer, Brighton, Sussex.

**TECHNICIAN OR JUNIOR TECHNICIAN** for research work in the Pathology Department—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

**VIROLOGIST** (or a Biologist with some virological experience) to work on a joint research enterprise between the National Institute for Medical Research and the Department of Biochemistry, Imperial College. The work will involve study of antiviral substances in animals and in tissue culture—The Director, National Institute for Medical Research, Mill Hill, London, N.W.7.

## APPLICATIONS OF SCIENCE AND TECHNOLOGY TO DEVELOPMENT

THE Advisory Committee on the Application of Science and Technology to Development was established by the Economic and Social Council of the United Nations in January 1964 to follow up the work of the conference on the "Application of Science and Technology for the Benefit of the Less Developed Countries", which was held in Geneva early in 1963. Its eighteen members, appointed in their personal capacity, include Prof. S. A. Anderson of Denmark (chairman), Dr. P. A. Auger (France), Sir Ronald Walker (Australia), Prof. O. L. Wilson (United States) and Sir Norman Wright (Great Britain). A preliminary report was issued last year, but its second report, which represents the main outcome of the Committee's work so far, was issued in May 1965. It calls for a concerted attack, using the latest techniques, on selected problems which impede social and economic problems in the developing countries. Although subsequent sections of the report deal with international co-operation in science and technology generally, the outstanding section is that which outlines in some detail major scientific and technical problems in eight selected fields which, the Committee suggests, merit special attention and a concerted attack.

In these eight fields, the acquisition of new knowledge is of primary importance, in contrast to the wider and more intensive application of existing knowledge, suitably adapted to local conditions, which, in the Committee's view, provides the best prospect of securing rapid advance in the developing countries. They are: (1) the provision of adequate food supplies; (2) the improvement of health; (3) the fuller understanding of population problems; (4) the most effective exploration and utilization of natural resources; (5) industrialization; (6) housing and urban planning; (7) improvements in transport; (8) education, including new educational techniques. These problems are, for the most part, of great interest and importance to the developed countries also, and this is particularly true of the group of problems bearing on food supplies, to which about a third of this whole chapter of the report is devoted.

The Committee considers that major improvements in the food supplies of the developing countries could be made by a concerted attack on four broad groups of problems: improvements in water resources; improvements in some applications of meteorology to agricultural production; improvements in the supplies of edible proteins; and the prevention of losses of food, as well as on one more specialized problem—the control of the tsetse fly and trypanosomiasis in Africa. While these are not all of particular interest to Britain, those concerning water supplies and conservation should be noted. The report points out, for example, that not only are geological appraisals necessary, but also the means of determining the velocity and direction of the flow of groundwater and of establishing underground connexions between different sources of water need further elaboration, including geophysical and electrical conductivity methods, and the extremely useful application of radioactive and stable tracers. Complementary to such surveys and investigations, the collection of hydrological data and their processes-

ing by the co-operative use of digital computers would be of the greatest value. Construction of underground barrages is also a potentially important sequel to such surveys, and the importance of the Geological Survey in this connexion is not always appreciated.

With regard to the prevention of water losses, the report points out that the efficiency of the control of evaporation by using monomolecular films is still only at the early experimental stage, and seepage control by cheap lining is, as yet, imperfect. Both these problems merit much more intensive study—the former in particular being of importance in conservation of what now in many countries is already a limited resource. While the need for more intensive investigations of the possibilities of breeding improved varieties of plants with minimal requirements for water—such as drought-resistant varieties, and of salt-resistant varieties capable of growth in brackish water or in brackish water partly diluted with salt-free water—may not be directly relevant to problems in Britain, it does serve to emphasize the importance of more efficient utilization of natural resources.

Desalination, however, is another matter. The Economic and Social Council has particularly stressed the importance of desalinating brackish and sea-water. The real problem still to be faced, and with which the report is specially concerned, is the possible use of such water for agricultural production. While the Committee recognizes that the first priority in this field must continue to be the provision of fresh water for direct human needs, the major problem is to find desalination processes capable of application in agricultural production and particularly, in the longer term, for irrigating staple field crops. The Committee suggests that special attention should be directed to this problem.

It should be noted that, speaking in the House of Commons on July 14 in the debate on the Ministry of Technology, the Minister, Mr. F. Cousins, referred particularly to the programme of desalination research on which the Atomic Energy Authority was now working in collaboration with industry. The programme is expected to cost some £1.5 million in the next three years and the Minister of Land and Natural Resources, Mr. F. T. Willey, has already directed attention to the necessity of considering the use of desalinated water to meet some industrial demands. The Water Research Association, moreover, is expected to submit an interim report on the potentialities of desalination to the Water Resources Board some time this year, and the Association's staff is already working with Government support on a three-year feasibility study.

As regards improvements in the application of meteorology, the Committee directed special attention to improved weather forecasting and welcomes the initiation by the World Meteorological Organization of the World Weather Watch as likely to be of outstanding value to the developing and developed countries and meriting the fullest support. If the full co-operation of all countries could be assured, the Committee considers that the World Weather Watch would be a most valuable example of the benefits to be achieved by a world-wide application of

science and technology for the common good. The hope is expressed that those countries possessing weather satellites will consider favourably the great benefits which they might confer on the developing countries by extending and adapting their observations and computations to the tropical areas. The Committee recommends that training facilities for scientists in both developed and developing countries should be substantially strengthened and that the provision of more adequate incentives to potential trainees in this field should receive high priority.

Concerning the future development of ways of modifying and controlling weather, the Committee agrees broadly with the recommendation put forward in a report from the National Science Foundation, that there are three main goals for this purpose: (1) the attraction of new creative talent to research in this field and to the atmospheric sciences as a whole; (2) a wider attack, by means of greater support for theoretical and field research, and with fresh emphasis on the long-range investigation of the modification of climate and weather, on both regional and continental scales; (3) a shortening of the time gap between the development of theory and the start of field research so that new techniques can be tested as soon as a sound theoretical basis is established. A wise reservation was expressed, however, that in this field particularly it is essential that the most careful study should always be made by international study and agreement of the balance between possible risks and benefits: in this the Committee is fully supported by the whole trend of the Commoner Report on the integrity of science (*Nature*, 206, 1277; 1965).

So far as edible proteins are concerned, one aspect of the improvement of supplies appears to be attracting attention in Britain, namely, the production of protein from fisheries. While this is even more important in tropical countries, the Committee suggests that the first and basic need is to initiate a world-wide co-ordinated survey of fisheries resources. It suggests that, in view of the great importance of increasing the supplies of edible fish, it is now essential to make such a world-wide effort to locate and estimate those resources by international co-operation. It also directs attention to the importance of the production by industrial processing techniques of foods rich in protein. While the technical problems in the production of such foods have largely been solved, there are two major obstacles: first, a marked resistance on the part of consumers to protein-rich foods in the forms in which they are at present produced from unconventional sources, and, secondly, the reluctance of manufacturers to venture into the commercial production of such foods. The Committee suggests, therefore, that there is room for imaginative developments in producing industrially processed protein-rich foods, and designing them to meet the existing food habits of the developing countries where they are to be marketed. The urgency of this need, in the Committee's view, demands that methods in which success has already been achieved should be closely studied and, if possible, applied on a much larger scale.

As regards prevention of food losses, what is required, the Committee believes, is not a concerted attack in the search for basic new scientific principles but rather a study of the means by which such principles can be applied to particular circumstances in different countries. There is a special urgency to determine the best means of adapting existing knowledge to small-scale methods of storage and preservation, using facilities which can be made available within a village community or on an

intermediate scale in rural collecting and distributing centres. It is suggested that the use of radiation in the preservation of food and disinfection of grain has shown sufficient promise to justify very careful examination.

With regard to the control of the tsetse fly, the Committee urges that high priority should be given to scientific studies of trypanosomiasis in Africa, and to the measures afterwards needed to apply the results on a sufficient scale. Much closer integration of the different approaches to reclamation and rehabilitation of affected areas is essential if they are to be applied. Further research on both the basic and applied aspects of science relevant to trypanosomiasis, on the improvement of methods of control by drugs and insecticides, as well as on the ecology of the vector itself, is essential if new and more effective techniques of controlling the disease are to be achieved. The Committee hopes that adequate academic and financial support will be given to universities and research organizations in Africa and elsewhere to encourage them to develop training facilities for African workers in this field.

This leads the Committee to pass naturally from questions of food supply to the consideration of measures for the improvement of health. It is here that it emphasizes the relation between pure-water supply and water-borne disease, and points out that provision of an adequate and pure-water supply in the developing countries is a matter of the first priority. It does not appear possible, however, to define any one water-borne disease on which a breakthrough might be envisaged by concerted attack; the Committee suggests that such diseases should be left, as hitherto, to the normal programme of the World Health Organization.

On population problems, the Committee's examination of available evidence leads it to the opinion that further research on a world-wide scale is desirable on demographic, social and economic interrelations; on human reproduction and means for its regulation; and on communications in relation to problems of population. The Committee recognizes that the intensity of such problems varies from country to country and that ultimate solutions involve considerations that go far outside the scope of science. It welcomes the arrangements being made for a World Population Conference under the sponsorship of the United Nations in Belgrade this year, and endorses the proposals for co-operation in research in this field made in a recent memorandum from the Secretary-General to the *ad hoc* Committee of Experts.

As regards the exploration and utilization of natural resources, it is recommended that more attention should be directed to the natural resources of the developing countries, especially by scientific methods; this is regarded as a research area calling for some priority. The Committee also considers that more effective measures are still required to implement the findings of the United Nations conference on "New Sources of Energy", held in August 1961, both by the countries concerned and by the United Nations itself. Besides nuclear power, these possibilities include solar energy and geothermal energy, as well as tidal energy. While the Committee fully appreciates the importance of industrialization in development and has sought the advice of the United Nations Centre for Industrial Development, it is concerned more especially with developments appropriate to the particular conditions of the developing countries, through the use, for example, of local materials and of an appropriate relative input of

labour and capital. The Centre suggested that the main steps to be taken included the strengthening or establishment of appropriate research institutions, together with the development of suitable procedures for referring problems between industry and such institutions, including appropriate government policies. More attention should also be directed to the special requirements of the developing countries for machinery and equipment. The indigenous raw materials of such countries also present special technological problems in their processing for domestic and export markets.

In the field of housing and urban planning, the Committee suggests that the migration in the developing countries from rural to urban areas offers a problem of outstanding importance in settlement as well as an ideal opportunity for applying the techniques of operational research. The industrialization of building presents a further opportunity, calling both for more rapid techniques of building than at present exist in the developing countries and for further research, not only in science and technology but also in design and methods of production. Coordinated research on a world-wide basis is also recommended into needs, materials, design and mass production and distribution of roofing in tropical areas. With respect to transport, the Committee was concerned with the construction of roads and of vehicles suitable for use in the rural areas, though, in view of the increasing importance of sea transport to the developing countries, it suggests an enquiry into the turn-round of shipping at ports to determine more fully the nature of the problem and the possibility that research within the Committee's field of competence might assist. So far as roads are concerned, research is urgently needed to improve methods of soil stabilization and to determine the relative effectiveness of different stabilizing aspects with different varieties of soil. Better means for undertaking accelerated tests on such methods of stabilization would greatly assist such investigations. Further investigation of methods of devising vehicles specially suitable for use in rural areas where road surfaces make transport particularly difficult is also regarded as worth while.

Finally, the Committee recognizes the great obstacle to development which adult illiteracy presents in the developing countries and the urgent need for rapid adoption of means to reduce illiteracy. It suggests that the initial step for such countries should be a survey of existing needs and resources and the development of methods and media for adapting and using available resources to meet local conditions and needs. It welcomes the plans of Unesco to expand projects in teaching physics into those of chemistry and biological science, though it believes the scale of expansion is inadequate. It places the highest priority on measures designed to raise educational levels throughout the developing countries, and particularly on the initiation, development and application of new educational techniques, however novel in their conception.

Although the proposals for new work are concerned essentially with the developing countries, it is manifest that at several points they are in line with developments which are already taking place in some developed countries. That in itself could facilitate co-operation, and beyond this the Committee presents its proposals as essentially a programme of international co-operation, fully in line with the present-day scientific and technological activities of the United Nations and its related agencies. It believes that a new programme of this

magnitude is not only possible but also highly desirable. The programme should embrace co-operation in promoting education in science and technology and training scientific and technical personnel in the developing countries; in strengthening the links between universities, research institutes and laboratories in developed and in developing countries; in studies and research on priority problems; and in providing technical assistance to the developing countries.

The Committee considers that more information regarding particular institutions and forms of co-operation is needed as a basis for planning new activities; however, it does not think that a new organization for the purpose of gaining such information is necessary or desirable. The Economic and Social Council would itself be the appropriate body, under the authority of the General Assembly, to initiate and guide the programme. Nevertheless, in a reference to the availability of manpower and resources the Committee puts its finger on the weak spot. Apart from the financial instability or weakness of the United Nations, the proposals put a severe burden on the highly skilled manpower which is already severely strained in the developed countries. The former might be eased—given goodwill and acceptance of their full responsibility by members of the United Nations. The latter is a problem that is not easily removed without much closer attention being paid to the use of scientific and technical manpower as well as to its training.

Nevertheless, in this report the Committee sounds a confident note. It welcomes the constructive self-examination already being undertaken by the organizations of the United Nations. This is an essential first step to expansion in fields where activity is still low, and the Committee also emphasizes that evaluation should cover failures as well as successes. It notes the central place which scientific policy on the part of Governments must take, and, while it welcomes particularly the survey of co-operation between universities and scientific and technological institutions in different countries which Unesco has undertaken, it considers that co-operative links should be encouraged and extended to other fields. Such fields should include, for example, engineering and public utilities, and liaison between semi-government and non-government agencies concerned with science and technology. It notes that even between universities a long-term rather than a short-term approach is desirable, and it suggests that Unesco should examine the desirability and practicability of establishing liaison bureaux to facilitate contact between institutions in developing and developed countries.

Given the funds and scientific staff, as well as sufficient authority, the Committee believes that it can move ahead with confidence along the lines indicated in this report and it is proposed that a series of working groups will enable the Committee to keep progress under review, handle the problem of information, and accelerate the critical programme of education, as well as keeping in touch with whatever action its individual members may take. The report is now, it is understood, being considered by the Economic and Social Council and it is clearly important that the Committee's conclusions and recommendations should be widely discussed by scientists and technologists throughout the world. Only if such professional opinion is wholeheartedly behind the programme can its proposals have any hope of real success; but when all allowance is made for the present difficulties of the United Nations the report presents a challenge which deserves a strong and imaginative response.

## ENRICO FERMI

Enrico Fermi

*The Man and his Theories.* By Pierre de Latil. Translated by Len Ortzen. (Profiles in Science.) Pp. 178+Illustrations. (London: Souvenir Press, Ltd., 1965.) 21s.

THIS is another book in a series of concise works each of which deals with the life and work of a scientist. Pierre de Latil tells the story of Fermi's life, with ample detail to bring the man to life without swamping the explanations of the scientist's achievements.

As a young Roman student, Fermi began studying when the first explanations of the new physics had gained acceptance. He was able to build on this work to such an extent that he participated in most of the following stages of the discovery of atomic energy. In particular, he was responsible for the design and construction of the first self-sustaining uranium-graphite pile set up underneath the grandstand of the squash court at Stagg Field, the University of Chicago Stadium, in 1942, and he was one of the chief figures in the making of the first atomic bomb.

In the first place he worked as a theoretician, but this led him to spend an ever-increasing time on experimental work. The lack of technical means for continuing his experiments forced him to become his own engineer. His ability in all three fields enabled him to tackle the vast problems which he considered. He could have re-organized the whole of Italian physics teaching, but the Dictatorship in his own country was no more tolerant and enlightened than that in Germany, and in 1938 he accepted an appointment at Columbia University, immediately after his award of a Nobel Prize, which actually assisted his escape from his native land. The United States, with its vast resources, suited his genius, but for a time he was regarded as an enemy alien and subjected to security control. Indeed, although he entered the United States with a Nobel Prize, he was subjected to an infantile examination in arithmetic. Fermi died philosophically and stoically from internal cancer at the age of fifty-three.

The translation of the book, though it projects the spirit of the original, is sometimes defective; for example, fluorine and nitrogen appear as fluor and azote, respectively. Some surnames, such as those of Wigner and Bethe, are misspelt.

The chronology of some of the events in the history of atomic physics is open to question. For example, the discovery of artificial radioactivity in 1934 is described as the "first time that man had provoked activities within the nucleus of the atom". Cockcroft and Walton (1932) are not even mentioned, but the transmutation of the lithium atom might be regarded as a man-made nuclear activity. The discovery of radioactivity by Becquerel early in 1896 is described as "through pure instinct as an experimental physicist". It is surely well known that Becquerel read Röntgen's X-ray paper of December 1895, and this suggested to him an experiment of a complementary nature, which, while it did not give the expected result, quickly led to the discovery of the phenomenon of radioactivity.

This useful book is well produced and contains many good illustrations.

W. L. SUMNER

## WAVE PROPAGATION THROUGH THE IONOSPHERE

*Lectures on Modern Magneto-Ionic Theory*

By K. G. Budden. (Documents on Modern Physics.) Pp. 82. (London and Glasgow: Blackie and Son, Ltd., 1964.) 30s.

THE purpose of this book is to introduce advanced students to the theory of wave propagation through the ionosphere. This transmitting medium is both

absorbing and doubly refracting, and it often varies with distance neither slowly nor quickly compared with a wavelength; an understanding of how waves travel through it therefore involves consideration of several fundamental ideas of considerable complexity. The book includes, for example, discussion of wave packets, group velocity, signal velocity and energy velocity, resolution into angular spectra, the relation between ray surfaces and refractive index surfaces, the impulse response of transfer functions, Sommerfeld precursor waves, reflexion coefficients and their relation to characteristic admittances, WKB solutions, phase integral methods, and the methods of steepest descent. Although the topics discussed are of immediate importance for ionospheric theory they are treated so generally that they can be applied immediately to the propagation of other kinds of waves.

Dr. Budden has not attempted to write a mathematical text-book; to some extent he assumes that the basic theory has been studied elsewhere and his aim is to discuss it for the purpose of understanding the physical behaviour of the medium and of the waves. His book will help the advanced student, for whom it is intended, to realize that mathematics is not just a substitute for an automatic computer which provides the 'answer', but if it is followed intelligently step by step it also provides a precise description of the physical processes concerned. It is a guide rather than a text-book and, because it is based on a lecture course, it is ideally suited for its purpose. Dr. Budden, well known as a lecturer and a director of research students, has performed a considerable service in making some of his best lectures available more widely in this way.

The book can be recommended to all those who work in the complicated subject of wave propagation through magneto-plasma. Beginners will use it to help them to understand text-books and papers; established workers will use it to clarify their ideas; and experts will read it to admire the way in which the essentials of a problem are exposed in all their simplicity. Those who believe they have fully understood a problem when they have discussed it with the help of a complicated piece of mathematics will learn from this book how it is possible to acquire an even deeper understanding through a detailed discussion of what the analysis means.

J. A. RATCLIFFE

## CHEMICAL REACTIONS OF POLYMERS

*Chemical Reactions of Polymers*

Edited by E. M. Fettes. (High Polymers: a Series of Monographs on the Chemistry, Physics, and Technology of High Polymeric Substances, Vol. 19.) Pp. xxii+1304. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1964.) 300s.

CHEMICAL reactions of high polymers are of considerable scientific and technological importance. Knowledge of reactions that may occur during processing, exposure to heat, light and other forms of radiation, and to oxygen or ozone, is essential to an understanding of the factors governing polymer stability in different environments. Technological applications of high polymers have been greatly extended by the use of such reactions as those causing cross-linking, the combination of different polymers and modification of structure and therefore of properties. Although many of these reactions have been known for a long time and, with others, have been extensively studied, the general subject of chemical reactions of polymers has not previously received separate treatment. This book, intended for graduates in chemistry and in which a knowledge of the structure and properties of polymers is assumed, is designed to give a critical survey of the various types of reaction in which at least one re-

actant is a high polymer. Forty-seven contributors, drawn from the United States, Great Britain and France, provide sixteen chapters, each of the latter generally covering either a type of reaction common to many polymers or reactions of a particular polymer or group of polymers.

The first chapter provides a general discussion of reactions and reactivities of polymer functional groups and of some of the factors affecting reactivity. The second deals with reactions of unsaturated polymeric hydrocarbons and is, perhaps inevitably, largely concerned with reactions of rubber. Isomerization, cyclization, addition of thiols, halogenation, epoxidation and hydrogenation are among the topics covered. A shorter chapter on reactions of saturated polymeric hydrocarbons includes poly-olefine substitution, reactions involving halogens and side-chain and nuclear substitution in polyvinyl aromatics. A chapter concerned with addition polymers containing reactive terminal groups deals separately with the production and reactions of such polymers produced by free radical and ionic mechanisms, consideration of the latter including 'living' terminal groups.

Two chapters are devoted to reactions of natural polymers. One, dealing with cellulose, gives a useful review of degradative and substitution reactions and a brief account of cellulose as a substrate for vinyl graft polymerization. The other is longer; it is concerned with proteins, and deals in some detail with protein structure, reactions of side-chain and main-chain groups, cross-linking, grafting and the effects of high-energy radiation on proteins.

Different types of interchange reactions of polyesters, silicones and polysulphides form the subject-matter of one chapter, and another, on cleavage reactions, deals with hydrolysis of polyesters and polyamides, the thermal degradation of polymers generally, and degradation resulting from irradiation and ozonization. Cross-linking is considered in a chapter on intermolecular reactions which includes cross-linking by irradiation and by monomers, their effects on structure and properties and cross-linking of elastomers. An account of branching reactions covers self-branching in the polymerization of ethylene, vinyl monomers and dienes and also graft copolymerization in some detail. Coupling reactions form the subject of another chapter in which polysulphides, epoxides, polyurethanes and related isocyanate polymers are considered. A chapter on surface reactions, largely concerned with surface grafting, includes a brief account of chemical treatments of polymer surfaces. A short account of oxidative reactions deals with polymeric hydrocarbons, including consideration of antioxidants, halogen-containing polymers, vinyl and condensation polymers. Mechanochemical reactions are reviewed in a short chapter. The last two chapters, dealing with fibre-reactive dyes and chemical finishing of cellulosic fibres, are more technological in nature. Extensive bibliographies at the end of each chapter generally cover journals, books and patents up to 1963 and also provide references to *Chemical Abstracts* for abstracted patents, for most non-American references and for other less readily accessible ones.

Among the factors to be considered in assessing the value of a book of this type are the arrangement, balance and possible overlapping of contributions and, in these days of an information explosion, the availability of the information from other sources. The scope of the book and the need of groupings for which suitable contributors could be found have led, as the editor points out, to a hybrid system of arrangement. There are inevitable differences in style and approach, but variations in level and character between different contributions are not usually very great. The last two chapters seem rather out of keeping with the rest of the book and might perhaps have been omitted. Overlapping is not serious and where certain topics, such as hydrolysis and grafting, appear in more than one chapter they usually refer to different polymers. A more serious criticism, perhaps, is that some

topics, for example the reactions of cellulose and of rubber, thermal degradation and mechanochemical reactions, are well covered in other books. Their inclusion, in some cases as relatively short reviews, may perhaps be justified in that it enables the book to provide a useful survey of the principal reactions of high polymers. It should be of considerable value to both academic and industrial polymer chemists although its high price makes it unlikely to be included in their personal libraries. W. R. MOORE

## A CLASSICAL BOOK ON ANALYTICAL DYNAMICS

### A Treatise on Analytical Dynamics

By L. A. Pars. Pp. xxi + 641. (London: Heinemann Educational Books, Ltd., 1965.) 147s.

THIS volume represents the distillation of the life work of a Cambridge mathematician of the old school who devoted himself mainly to that realm of science that has engaged the attention of great applied mathematicians down the ages ever since its inception by the supreme master of them all. The author can well be proud of the beautiful achievement that is this book. L. A. Pars spent his working years as a genuine full-time don, undistracted by extramural activities and the anarchic scramble for 'recognition'; he remained cloisteredly devoted to College and Faculty, the latter so much so that he retired from it when there began the end of the great traditional standards so carefully built up and maintained this century past.

In these days of speculative discovery it is sometimes almost forgotten that gravitation remains the principal governing force throughout the universe, and that accordingly dynamics as such can never lose its importance. As I write these lines a space-ship is hurtling towards Mars guided on an astronomical course of unerring precision by methods that no one would dream of querying, so secure is the basis in Newtonian mechanics. That dynamics has largely been superseded by relativity as an academic subject for study in no way lessens its importance, and it is far from generally appreciated how little is known and how numerous are the unsolved problems in the great field of celestial mechanics. Moreover, relativity has yet to provide explicit workable rules remotely comparable with those of classical mechanics that can actually be applied directly to real problems.

The present volume is a masterpiece of scholarship and erudition in which the structural elegance of pure mathematics is brought to the presentation of the whole realm of classical dynamics. It eminently succeeds in its intended objective, which is to give a compact, consistent, and reasonably complete account of analytical dynamics as that subject now stands. The treatment adopts as its fundamental basis the virtual-work equation:

$$\sum (m_r \ddot{x}_r - X_r) \delta x_r = 0$$

of Lagrange, and developing this into various equivalent forms shows how these have their own special utility and suitability for particular domains of the theory. Pars develops each of these areas with sufficient completeness to equip the reader with the fundamental ideas and relevant techniques and enable him to proceed to further study and research.

The net result is a massive tome of transcendent worth, and though it is so much more than a text-book one must hope that present-day students will put themselves in the way of benefiting from it. One is reluctant to think that it may perhaps be too voluminous to appeal to students to-day, when the brief pocket-volume is so much more in keeping with the lines along which they are now being encouraged in their headlong demand for short-cut education. For the same reason, it is perhaps to be regretted that sets of illustrative examples do not round off the end of each chapter and that comparatively few

worked examples figure in the text, for surely it is only by such means that a reader can make certain that he understands how to apply the theory, however seemingly perfectly and extensively he may be able to reproduce it. The book can be unhesitatingly recommended to all—student, teacher, research-worker, professors, and others—and in the hope that a second edition is called for soon perhaps Mr. Pars could meanwhile collect and supply some examples further to enhance the value of this remarkable book.

R. A. LITTLETON

## THE BRITISH ISLES

### Field Studies In the British Isles

Edited by Prof. J. A. Steers. Pp. xxiii + 528. (London: Thomas Nelson and Sons, Ltd., 1964.) 70s. net.

### The British Isles

A Systematic Geography. Edited by Prof. J. Wreford Watson and Dr. J. B. Sissons. Pp. xii + 452. (London: Thomas Nelson and Sons, Ltd., 1964.) 45s. net.

WHEN the twentieth International Geographical Congress was held in the United Kingdom during July–August 1964 and attended by some 2,200 delegates, it followed the pattern laid down by the preceding Congress held in the five countries of Norden in 1960. The week of main meetings, opened by Her Majesty The Queen, accompanied by His Royal Highness Prince Philip, in the Albert Hall on July 21, was preceded and followed by specialist symposia in different parts of the United Kingdom. In this way every university and many other institutions in the country had an opportunity of playing a part. There were no less than 33 such symposia; some were essentially regional—such as the meetings in the Channel Isles, the Outer Hebrides, or Ulster—others concerned themselves with a definite topic, such as the agricultural geography of Ireland, the geomorphology of Snowdonia, or urban growth in Yorkshire and Lancashire, while still others were wide-ranging, such as geography in the National Parks, or the eight-day study tours of Ireland and Scotland.

*Field Studies* is a substantial well-produced volume of 528 pages, fully illustrated with maps and diagrams, which provides the essential background material to these symposia and study tours. Whereas previous Congresses have issued 'excursion guides' of a more or less ephemeral nature, this volume has both a permanent and topical value not only because it affords regional descriptions by the experts on the spot, but also because the itineraries followed could scarcely be bettered by anyone wishing to see on the ground the various aspects of Britain's geography. There is one chapter only on London, but the varied aspects of London's geography, seen by many during the main Congress, are covered in *Guide to London Excursions*, edited by K. M. Clayton (obtainable from the London School of Economics, 21s.).

All full members of the Congress were also presented with a volume of *Abstract Papers* (with supplement) edited by F. E. Ian Hamilton (now obtainable from Geographical Publications, Bude. 7s.) and in due course will receive the *Proceedings*, but they also received on registration *The British Isles*, a finely produced volume to which 23 leading British geographers have contributed. Among the standard works already in existence, *The British Isles*, by L. D. Stamp and S. H. Beaver, now in its fifth edition (Longmans, 1963), covers in sequence the varied aspects of the geography of the British Isles, and *Great Britain: Geographical Essays*, edited by Jean Mitchell (Cambridge, 1962), deals with the country by regions. Consequently, the Editorial Committee felt that the Congress volume should take up topics in sequence. Thus, the senior editor contributes a first chapter on the "Individuality of Britain", and is followed by R. W. Steel on "British Geographers", G. R. Crone on the "Mapping of

Britain", S. Gregory on "Climate", W. G. V. Balchin on "Hydrology", and so on. While there are chapters which cover the usual—such as "Relief and Structure" (G. T. Warwick) or "Agriculture" (W. R. Mead)—all have a freshness of approach and presentation; other contributions reflect new and developing aspects of study, such as Emrys Jones on "Cultural Geography".

Modern geographers commonly accept that their study is essentially that of the relation between man and his environment, a relationship which has undergone a complex evolution through the ages and which projects itself into the future in the realm of physical planning. Those geographers who concern themselves with the physical background, whether the relief of the land or the vagaries of climate, have become increasingly aware of the importance of minutiae. This is well brought out in the three chapters: "Tertiary Landscape Evolution" (D. L. Linton), "The Glacial Epoch" (J. B. Sissons) and "The Evolution of the Climatic Environment" (G. Manley). The essays which follow are nearly all heavily weighted on the historical side—from prehistoric (E. E. Evans), pre- and post-industrial revolution (H. C. Darby and R. Lawton) to the present-day problems of land use (J. W. Birch and J. T. Coppock) or the mineral industry (S. H. Beaver) and industry (E. M. Rawston).

As with all such collections of essays, the specialists expand on their own interests—A. E. Smailes on towns, A. O. O'Dell on transportation, H. Thorpe on rural settlement, and R. H. Osborne on population, but, thanks to skilful editing, obvious gaps are few.

The Congress has thus made a notable contribution to geographical thought: it has adequately supplemented, rather than replaced, existing works, and Britain is now well served by the range of books available.

L. DUDLEY STAMP

## THE FUNGI

### Die Pilze

Grundzüge ihrer Entwicklungsgeschichte und Morphologie. Zweite, umgearbeitete und erweiterte Auflage. Von Prof. E. Gellmann. (Reihe der Experimentellen Biologie, Band IV.) Pp. 541. (Basel und Stuttgart: Birkhäuser Verlag, 1964.) 66 Sw. francs.

THIS is the second edition of *Die Pilze*, first published in 1949 and translated into English by Wynd in 1952. The second edition is some 120 pages longer than the first and contains 170 more illustrations. In content the book is modelled closely on its predecessor, but there has been considerable revision of the classification of Ascomycetes. The emphasis throughout is on morphology and life-cycles. Attempts to interpret the probable course of evolution to elucidate phylogenetic relationships are frequently represented in the form of phylogenetic trees. The evidence of such interrelationships is often very slight, and although the suggested relationships are qualified as conjectural, there is a danger that they will become accepted as established.

Apart from the notable omission of the Fungi Imperfecti, dismissed in little more than a page, and the lichens, most groups of fungi have been dealt with. The classification of the 'Phycomycetes' does not reflect recent thinking (see, for example, the work of Sparrow), and the group Archmycetes is retained for holocarpic zoospore forms. This has the unfortunate effect of separating *Olpidium* and *Synchytrium* from the Chytridiales. The Saprolegniaceae, Peronosporaceae and Leptomitaceae are treated as families of the Oomycetes, while the Mucoraceae, Endogonaceae and Entomophthoraceae are treated as families of the Zygomycetes, instead of being accorded original rank.

The classification of Ascomycetes has been radically revised, with the structure of the ascus wall emphasized as a primary criterion of separation. Three sub-classes

are proposed: protunicate, unitunicate and bitunicate Ascomycetes. The protunicate forms are those in which the ascospores are not violently projected, and the ascus walls of which break down when the spores are ripe. Although this novel proposal has some merit in that it directs attention to the ascus wall, it is doubtful if the protunicate Ascomycetes represent a natural assemblage, because such diverse groups as the Endomycetales, Aspergillales, Microascales, Coronophorales, Onygenales, Meliolales and Laboulbeniales are included.

Some modification to the classification of Basidiomycetes has also been made. There are two sub-classes, the Holobasidiomycetes and Phragmobasidiomycetes. Within the Holobasidiomycetes the following groups are included: Aphyllophorales, Agaricales, Agaricogastreales, Gastreales, Phallales. The account of the Agaricogastreales is especially useful. The arrangement of the Phragmobasidiomycetes is more conventional, embracing Tremellales (inclusive of the Dacrymycetaceae), Auriculariales, Uredinales (with a masterly account of variation in life-cycles) and Ustilaginales.

Although the second edition is considerably longer than the first it is unfortunate that no space has been devoted to some recent developments. For example, there is no reference to the role of *Olpidium* as a virus vector, and the demonstration of heterothallism in *O. brassicae*. The appearance of new biotypes of *Synchytrium endobioticum* is ignored. The whole question of physiological specialization of pathogenic fungi is scarcely mentioned. Very little notice is given to the fine structure of fungi apart from figures of flagella of *Allomyces* and *Saprolegnia*. No details are given of fine structure of cell walls, septa, haustoria, or of yeast cells. Sansome's claims that some Saprolegniaceae and some Pythiaceae are diploid are not discussed. Sexual reproduction in the Mucorales is dealt with very briefly, and without reference to the work of Banbury and Plampel, or to the variation in content of germ sporangia in relation to mating type. The relationship of *Endogone* to phycomycetoid mycorrhiza is not mentioned. In the account of the Entomophthorales there is no mention of the variety of methods of conidial propulsion, and only the secondary adhesive conidia of *Basidiobolus* are figured. The relationship of certain Ascomycetes to their conidial states is treated very briefly. Although *Cephalosporium* and *Gliocladium* are mentioned as conidial states of *Hypocrea*, there is no mention of *Trichoderma*. It is not made clear that the macroconidia of the Hypocreaceae are phialospores, and while it is true to say that some *Ophiobolus* and *Leptospharia* species have *Phoma*-type pycnidia there are at least five other form-genera known. The genetical treatment is weak. There is no mention of heterothallism in yeast, of heterokaryosis and parasexuality in *Aspergillus* and *Penicillium*, of the tetrapolar condition or multiple alleles in Basidiomycetes. The function of the clamp connexion in ensuring redistribution of two compatible nuclei in a hyphal tip is not explained. Alternative suggestions for the mechanism of basidiospore discharge are not discussed, nor are the observations that basidiospores often carry an electrostatic charge. The significance of the divided gill of *Schizophyllum* is not given. There is no account of hyphal structure of polypore fruit bodies.

Many of the illustrations appeared in the earlier edition, copied from other authors. The best of the new figures are from the pen of E. Müller illustrating Ascomycetes. Although it is liberally illustrated, more half-tone photographs, especially of pathogenic fungi, would have further improved the text. A student would, for example, learn little of the habit of *Plasmidiophora basicae*, *Phytophthora infestans*, *Albugo candida*, *Entomophthora*, *Taphrina* or the Ustilaginales. An irritating feature is the occasional use of different names for the same organism in figures and text, for example, *Pyronema omphalodes* and *P. confluens*, and *Rhizina inflata* and *R. undulata*.

There is a similar inconsistency in the use of *Agaricus* and *Psalliota*.

To sum up, this is not a book for a beginner. It lacks excitement and neglects many features of the 'biology' of fungi. As a source of ideas on phylogeny it is valuable provided that the ideas are treated with due caution. The style is terse and authoritative, and apart from a few minor errors and misprints, its chief defects are in its omissions. It is well produced, but at 66 Swiss francs (£5 7s. 3d.) it seems rather expensive. JOHN WEBSTER

## GERMAN AND ENGLISH DICTIONARY OF PHYSICS

Dictionary of Pure and Applied Physics

Compiled by Dr. Louis de Vries and W. E. Clason. Vol. 1: German-English. Pp. 367. 1963. Vol. 2: English-German. Pp. 341. 1964. (Amsterdam, London and New York: Elsevier Publishing Company.) 55s. each volume.

In these two volumes, two of the leading scientific lexicographers of the present day have combined their efforts and produced a compact work of reference giving a good coverage of the field of pure and applied physics (a field which certainly lacked such a dictionary hitherto). The number of terms on each page is 80-100, and so it can be seen that in more than 300 pages a very considerable vocabulary is presented. Although this includes words such as *stehen* and *stellen*, and phrases such as *wie immer*, the very great majority of the terms belong specifically to the field of physics. Adjective-noun and most other phrases are entered under the first word, which is convenient, although cross-references from the other words might have been worth the extra space needed. Entering *stark gedämpft* under *stark* is not likely to be useful (and there is no corresponding entry at *schoach*); is there not a case for an indexed thesaurus arrangement rather than an alphabetical arrangement in dictionaries such as these?

Dr. de Vries's habit of omitting any distinction of meanings, though mitigated by the restriction to physics, is still in evidence ("*line*, Leitung, *f*, Stromkreis, *m*, Zeile, *f*, Linie, *f*, Schirmschrift, *f*"), although oddly enough there is some attempt to make the distinction with non-technical words: "*serious* (earnest), ernst"—*serious* (grave) presumably not being considered worth including, nor is it even given as an equivalent of *schwer* ('heavy, stout, strong, difficult').

The spellings are not always correct; one page contains "hydroxyle ions" (the same in the other volume) and "shell spektrum" (which becomes "shell spectrum" in the other volume). American spellings appear to be used throughout, with no mention of British forms. But British terminology (for example, *valve* rather than *tube*) appears more or less randomly; of the relevant entries beginning with *Röhre*, thirteen use *tube*, ten *valve*, six both (and three neither). The compilers do not name their sources, but the material thus seems to have been incorporated somewhat uncritically. Moreover, a check of one page taken at random in Volume 1 showed that about three-quarters of the entries are essentially identical with entries in de Vries's *German-English Science Dictionary*, third edition, which costs about the same, and so anyone who already possesses the latter book will probably not be getting much for his money if he buys Volume 1 of the *Dictionary of Pure and Applied Physics*.

I am myself concerned almost exclusively with translation into English, and the German-English volume has been mainly considered. The English-German volume is by no means a mere inversion of the other, and should be equally useful to translators from English into German; but let us hope that these do not include many of the "students in science and technology in the United States" for whom (according to the preface printed in both volumes) the dictionary is also intended. J. B. SYKES

## A SCIENTIST'S PHILOSOPHY

## The Philosophy of Science

A Systematic Account. By Peter Caws. Pp. xii+354. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1965.) 52s. 6d.

THIS book, as well as being attractively produced and clearly written, is full of suggestive material for instruction within the general range indicated by the title. It is indeed 'a systematic account', but it is a good deal more than that, and it is therefore on those additional features that the present review will focus attention.

The author divides his work into four parts: 1, "The Discovery of Theory"; 2, "The Structure of Theory"; 3, "The Validation of Theory"; and 4, "The Spectrum of Theory". From this plan, the reader learns quite naturally what science is, and to what extent it is conformable with the remainder of normal living and experiencing. Then, the pattern of exact thought emerges, with the consequent background of organization. After that, anybody who asks why it is that scientific method engenders confidence will find a good answer, and lastly (and more strictly philosophically) what problems have been solved, and what remains to be done. All this is extremely readable, presented with common sense, but without being particularly noteworthy.

Different in calibre, however, are Chapters 43 and 44, which cause the reader to become air-borne, and well away to a flying start on themes that really matter, especially in the present climate of epistemology. Thus, "The Unity and Diversity of Science" (43) and "Science and the Humanities" (44) are first-class contributions to what may still be called the theory of knowledge. The questions which they raise are so important as to warrant comment in some detail.

The initial tenet is that there must be a perpetual 'in-phase' relationship between logical and experimental frontiers—a species of mutual feed-back, which is in harmony with much of general system theory, as commonly understood. The next step is to realize that the logical and rational element needs a principle of economy rather than one of simplicity, leading to a degree of austerity closely linked with aesthetic satisfaction. It is only too true, as Dr. Caws remarks, that some scientific theories give an impression of the baroque (they have, one might add, occasionally become almost rococo). But this is largely a matter of touch, itself in need of prudent discipline. Practically, however, we must 'save the appearances', as the Greeks maintained. It is impossible to avoid some growth in complexity as knowledge advances, or more exactly, as new evidence accumulates. The time arrives when expansion becomes coercive. Thus, the shift from the simple gas laws to Van der Waals's equation is mentioned. This is a classic instance, and much was gained in the process (a refined version of the critical state, for example), but it is well known that a whole host of other formulae—one of them at least being a transcendental function—were propounded at about the same time, to improve on the unhappy plight of  $PV = RT$ . That 'Van der Waals' survived is as much as to say that it was the best 'fit', *ceteris paribus*. Nevertheless, it implied a lowering of standards of elegance.

The quotation from Pascal's *Pensées* is apt, namely, the difference between '*esprit de géométrie*' and '*esprit de finesse*'. Adherents to the former are in safe company with the logicians and Cartesians, whereas supporters of the latter approach very closely to toying with metaphysics, when it comes to the point. But "other ways of knowing the world", tiresome as they may be to the formalist, have satisfied axiological elements all through the centuries: indeed, they watch with eternal vigilance for any vestige of arrogance in scientific claims in regions wherein other kinds of awareness illuminate the part played by value in human life and relationships.

Chapter 44 goes to the root of contemporary discomforts in regard to liberal studies. Historically, one may still marvel at the virility of Magna Graecia; localized seats of learning throwing up important advances all along the Mediterranean shores. Concerning experimental techniques, it is certain that these were frowned on by the scholars, but in a rather subtle way. Seemingly, the objection was to application, in contradistinction to the careful questioning of Nature, with the sole object of revealing her secrets.

The particular power of Aristotelianism—at its best—is well displayed as a unity of knowledge, be it metaphysics, drama, or anything in between. The evils, as well as the benefits, of specialization were yet unknown. But one development, mentioned earlier in the book, namely, the philosophical system of St. Thomas Aquinas, did much more than merely re-edit Aristotle. It largely created natural theology, thus adding its own quota to the growing body of erudition, culminating in the renaissance and the gradual acceptance of a worthy standard of 'polite learning'. Dr. Caws is doubtless aware of the revival of Thomism, in twentieth-century form, which provides such a marked, if surprising, characteristic of much modern philosophy, both in Europe and in the United States.

These pages end on exactly the right note. Skills, be they scientific, philosophical, artistic and all the rest, are priceless possessions, and there is no need to set up rivalries between them. Time was when *parti pris* generated considerable heat between the devotees of Newton and Goethe. Luckily—and on the whole—charity, like entropy, tends to increase. F. I. G. RAWLINS

## CULTURAL DEVELOPMENT OF MAN

## History of Mankind

Cultural and Scientific Development. Vol. 2, Part 1, 1200 B.C. to 500 B.C.: Pp. xxxiv+313; Part 2, From about 500 B.C. to the Christian Era: Pp. xiii+314-664; Part 3, From the Beginnings of the Christian Era to About A.D. 500: Pp. xii+655-1048, maps and illustrations. By Prof. L. Pareti, P. Brezzi and L. Petech. (Published for the International Commission for a History of the Scientific and Cultural Development of Mankind by George Allen and Unwin Ltd., London, 1965.) 126s. per set of 3 volumes.

VOLUME 2 of *History of Mankind* takes the story of man's cultural development from 1,200 B.C. down to A.D. 500, 1,700 years that witnessed the fragmentation of the widespread cultural complexes of the second millennium B.C. into small regional cultural groups, the domination of certain political systems, and the emergence of great religious beliefs. To understand why this volume achieves a measure of both success and failure in its aims, we must examine its own story. The history of the writing of this volume is almost as complex as the historical events that it documents. Prof. Pareti was initially appointed as author-editor, with Prof. Brezzi and Prof. Petech as assistants. The draft text was finished in 1960, and after revision on recommendations from nominated specialists, the second draft was again circulated and additional material incorporated as editorial notes. Later six other authors contributed supplementary matter which appears in the text. Although considerable care seems to have been taken to preserve the continuity in content and style, it has clearly been impossible to eliminate all the interruptions where different authors are juxtaposed. This presents certain difficulties, but is at the same time the main reason for the success of the book because here, in one volume, we have the consensus of opinion about many problems of long standing, for example, the origin of the Etruscans. It is perhaps a comment on the state of our knowledge and understanding of pre- and early

historic events that such opinions are often so widely divergent.

The volume is divided into three parts: from 1,200 to 500 B.C., thence to the Christian Era, thence to A.D. 500. Each part is treated in similar vein, beginning with historical events, and followed by language, technology, organization, religion and literature with their related topics. From some aspects this arrangement is to be disputed, apart from the artificial separation of such subjects as politics and economy, because it is difficult to trace the cultural and scientific developments in any one chosen area. Certain aspects of certain areas cannot be considered, and America and the Pacific are badly neglected, but perhaps inevitably when they must compete with Greece and Roman Italy, from where much of the evidence treated here has been derived.

The aim of the volume is to present a general impression of the development of technology, political organization, religion and so on, over widespread areas. As a result, the facts that can be given to describe a specific situation in a certain region cannot be more than an abbreviated summary, and will not be of much use to one who is looking for basic factual material, although an extensive bibliography of Greek, Roman and Near Eastern literature is provided. Nevertheless, it is of the greatest interest and value to have certain aspects of cultural development brought together from different areas for comparison; the emergence and dispersal of Indo-European languages is reasonably well known, if not agreed on, but less so the complex evolution of writing systems. Of particular interest, too, may be the evidence presented here for the discovery of scientific principles and allied philosophies.

In my opinion, the volume falls between two stools; on one hand, the purely objective and factual presentation with full bibliographical references; on the other, the theory of developmental processes throughout the world. The book scarcely aims as high as the first, and the nature of its production, with many differing opinions and editorial comments added, interrupts the flow essential to the second. Nevertheless, it probably comes as close as any book could to success in both fields. J. M. COLLIS

## SOIL FABRICS

### Fabric and Mineral Analysis of Soils

By Dr. Roy Brewer. Pp. xiii+470. (New York and London: John Wiley and Sons, Inc., 1964.) 113s.

SOILS are identified and classified to a great extent by characters which are essentially morphological and can be observed in the field. The most important morphological characteristic is of course the division of the soil profile into horizons. Field observations of soil morphology even when supplemented by physical and chemical analyses do not, however, permit a sufficiently detailed and certain explanation of the processes involved in soil formation.

The need for a more precise analytical approach to pedology is expressed in the introduction to this book. Dr. Brewer directs attention to the soil material rather than the soil profile as the unit of study. The purpose of the book is to provide a system of description and classification of the phenomena observed in soils and to demonstrate the application of mineral analysis to studies of soil genesis.

Mineral analysis, dealt with in the first section of the book, is presented with an intentional geological bias and much of the information relating to mineral grains, for example the analysis of size and shape, can be found in standard text-books of sedimentary petrology.

Calculations of soil formation are discussed, with emphasis on the use of a stable mineral to estimate gains and losses of weight and volume and of a particular constituent

during soil formation. The equations proposed to calculate these changes in the soil profile seem unnecessarily complicated and could easily be worked out from first principles. The author argues convincingly in favour of using parent rock selected on the basis of mineral analysis of the profile as the parent material for evaluating profile development. There is no doubt that the present arbitrary recognition of weathered rock as parent material leads to serious errors.

The subject of mineral stability and weathering is examined on a somewhat empirical basis. Considering the significance of plasma in soil fabrics, it is a pity that the relations between mineral stability and atomic structure were not explored further. One surprising error in this chapter is the assertion that "the rate of weathering of mineral grains is directly related to surface area of the grains, that is, inversely related to size of grains" (p. 74). Specific surface must of course be intended. A chapter on the classification of rocks as the parent materials of soils, completing the section on mineral analysis, is of limited value and in some particulars inaccurate.

The valuable section of this book, making up more than three-quarters of the whole, deals with the structure and fabric analysis of soils with special emphasis on the description, classification and, to some extent, the interpretation of pedological features. Most of the phenomena described are best seen in thin section and they are particularly well illustrated with more than one hundred photomicrographs.

Much of the recent research in this field has been promoted by Dr. Brewer and his colleagues at the Soils Division, C.S.I.R.O., Australia. It is not surprising to find that this section is very largely based on their work and that several important papers have been included with little amendment. As the question might arise as to whether specialists would be prepared to pay over £5 for the convenience of having these papers in book form it is only fair to add that they make up only about one-quarter of the section.

The concepts of structure and fabric are clearly discussed with new definitions proposed for terms in common, but sometimes vague, use among pedologists. The following new definition of soil structure is essentially the theme of the book: "Soil structure. The physical constitution of a soil material as expressed by the size, shape and arrangement of the solid particles and voids, including both the primary particles to form compound particles and the compound particles themselves; fabric is the element of structure which deals with arrangement".

The main components of soil structure, voids, pedological features such as cutans and crystallaria, the soil matrix and peds are clearly described and carefully classified.

It is worth mentioning the author's proposal that the term 'ped' be restricted to those aggregates entirely enclosed by natural surfaces. Peds are thus recognized by their surface characters rather than by the mere presence of a population of units of similar size and shape. Most field workers would probably support this suggestion.

A chapter is devoted to a discussion of the role of fabric and mineral analysis in soil science followed by an appendix describing the techniques involved.

This book does not, as suggested on the publishers' jacket, provide a thorough understanding of soil genesis and this could not have been the author's intention. It cannot be recommended, therefore, to students with only a general interest in soil science. The book is the most comprehensive treatment of soil fabric analysis at present available and, with the reservations expressed here, it will be welcomed by pedologists. The fact that the soil fabric must be significant in soil/plant relationships will mean that reference to this work will benefit research workers in a much wider field. The book is well bound and printed. J. L. M. LAMBERT

## Societas Scientiarum Fennica

Commentationes Humanarum Litterarum, XXXIV, 1: *Muslim Death and Burial: Arab Customs and Traditions, Studies in a Village in Jordan*. By Dr. Hilma Granqvist. Pp. 287. (Helsinki: Societas Scientiarum Fennica, 1965.) 14.80 F. Marks.

ARAB customs in connexion with death and burial is the third work of a trilogy by Dr. Hilma Granqvist. The other volumes have dealt with *Marriage Conditions in a Palestinian Village* and *Childhood Among the Arabs*. It is important that the folklore connected with these matters should be collected now before it is too late. The unchanging East is changing rapidly and the old customs and rituals are being forgotten.

*Muslim Death and Burial* is divided into three sections: (1) mortality, death, burial, after the burial, and unnatural deaths; (2) burial and mourning; (3) songs at death and burial. Dr. Granqvist lived for various periods in Palestine, especially at Artas, a village to the south of Bethlehem, and there made friends with the people and gradually collected the ancient folklore from them. While the book is full of stories and customs, it lacks any connective thread. However, to collect and preserve the folklore has been Dr. Granqvist's purpose, and in this she has succeeded.

Perhaps one or two examples will illustrate the matter. From the Earth is obtained the dust of which man is created. But it is only a loan from the Earth and repayment must be made at the place whence came the dust. Difficulties thus arise when a man dies far away from where he was born. As a man is one of a family, his relations must see that his dust is duly collected and returned. Again, a woman who has lived for a long time in a far-away village, having come there perhaps as a stranger to many, may die in a far country. This is explained by the saying, "Her dust drew her"—implying that somehow or other the dust from which she was originally made must have come from this place. Again, a doctor cannot treat a woman until a formula has been pronounced which makes her into his sister. For if the man sees merely up to her knees sin has been committed. If she is his sister this does not matter.

The account of a burial is particularly interesting. No unclean woman must take part; indeed, everyone at the burial must be ritually clean. Those who have to touch the body must have made their ablutions before the prayer over the deceased is given. When a dervish goes into seclusion he takes with him seven barley loaves containing bran, water in a dark blue Gaza jar, and a rattle of dates. This is because the demon fears a jar of this sort and demons never eat bran. They also fear a white cock with ten toes.

The foregoing short extracts will give an idea as to what the work is about. One can only be thankful that someone has collected these customs and written them up before it is too late. M. C. BURKITT

## Physikalische Begriffe in der Klinischen Biochemie

Von Dr. Hans Koblet. Pp. xii+274. (Stuttgart: Georg Thieme Verlag, 1964.) 30 D.M.

MEDICAL students are on the whole notable for their aversion to anything faintly mathematical. Yet all lines of research require mathematics as a scientific tool and medical science is no exception, and *Physikalische Begriffe in der Klinischen Biochemie* would scarcely have been written had Dr. Koblet not felt that the medical research worker needed some special help to overcome his difficulties.

The first part of the book deals with basic principles, the definition of a molecule, of specific weight and density, principles of solutions, titrations, law of mass action and chemical equilibrium. Other parts deal with acids and bases and the laws of thermodynamics. Particular attention is directed to enzyme kinetics and the calculation

of the Michaelis constant of enzymes. Attention is also given to pools and turnover rates, to diffusion and the connexion between clearance and elimination constants in the blood stream. There is a mathematical appendix in which briefly but very clearly differential calculus and integrals are explained. No one can protect the medical research worker from the hard work which is required if he is to make up for omissions of his student days, but this book will help him to fill some of the gaps because everything is derived from first principles and no previous knowledge is expected. H. LEHMANN

## Annual Review of Nuclear Sciences

Vol. 14. Edited by Emilio Segre. Pp. vii+510. (Palo Alto, California: Annual Reviews, Inc., 1964.) 8.50 dollars.

THE volume under review consists, as is usual in this series, of a large number of articles on a wide variety of topics. Ten articles are devoted to nuclear and particle physics, and to their associated experimental techniques. Two articles discuss "Breeder Reactors" and "Modern Techniques in Reactor Design", one the "Chemistry of the Actinide Elements" and one the "Quantitation of Cellular Radiobiological Responses". This volume therefore follows its predecessors in its rather curious mixture of contents.

The nuclear physics articles are concerned with "Alpha Decay", "Electromagnetic Moments of Excited Nuclear States", "Recent Progress in the Theory of Nuclear Matter" and "Nucleon-Two Nucleon Reactions above 100 MeV". The first of these concentrates on nuclei near lead and those heavier than thorium, with particular reference to calculations based on nuclear shell models. The article on "Electromagnetic Moments" is the longest in the volume and aims to be a complete review. That on "Nucleon-Two Nucleon Processes" summarizes in rather gloomy fashion the present state of our phenomenology and understanding and makes a number of useful suggestions for further work.

Short articles on "Spark Chambers", "Dynamic Orientation of Nuclei" and "Data Systems for Multiparameter Analysis" are well written as introductions to their respective subjects. That on "Data Analysis in Particle Physics", however, is aimed at the experimentalist who, though already adept at the manipulation of his data, has little or no formal training in probability.

The article on the "Structure of the Proton" is written from the experimentalist's point of view. Though directed at the expert, much of it can be read with profit by the tyro. That on "Symmetries among the strongly interacting Particles" appears to me to be strictly for the highbrows.

The fraction of nuclear and particle physics articles in this volume is close to the five-year average for this Review. One must therefore wonder what is the virtue in the editorial board's eyes of a policy of including regular articles on such topics as chemistry, reactors, biology, etc. They cannot serve as a means of broadening the nuclear physicists' interests, for they are written on too high a plane and surely are quite likely to be missed by the people most likely to benefit from them. B. ROSS

## Yearbook of Astronomy, 1965

Edited by Patrick Moore. Pp. vi+203. (London: Eyre and Spottiswoode (Publishers), Ltd., 1964.) 25s. net.

THE *Yearbook of Astronomy* continues its well-established system of providing month-by-month information about the night sky. Some of the articles are rather interesting and one of the most pleasant is that of James Muirhead, "A Cycle of Clusters and Nebulae", which could be sub-titled "star gazing for pleasure". However, there seems to be a decline in the quality of the articles generally which it is hoped will be corrected when the next *Yearbook* is produced. D. McNALLY

## SUBMARINE FRACTURE ZONES, ASEISMIC RIDGES AND THE INTERNATIONAL COUNCIL OF SCIENTIFIC UNIONS LINE: PROPOSED WESTERN MARGIN OF THE EAST PACIFIC RIDGE

By PROF. J. TUZO WILSON, O.B.E.  
Department of Physics, University of Toronto

THIS is the fourth of a series of articles advancing the hypothesis that another class of strike-slip faults can exist besides transcurrent faults<sup>1-3</sup>. Transform faults, as the class has been called, can only exist, and must be expected, if areas of the Earth's crust are being absorbed into the interior in some places and freshly formed elsewhere. If they have not attracted much attention heretofore, it is because they are largely a feature of the ocean floors and most examples are partly or wholly submarine. The fracture zones which B. C. Heezen, E. T. Bunce, J. B. Hersey and M. Tharp<sup>4</sup> have recently described in the equatorial Atlantic have been cited as examples of dextral, ridge-ridge, transform faults related to the growth of the Atlantic Ocean, and it has been suggested that these fracture zones join points on opposite coasts which were once in contact. Such points may be called conjugate.

### Three Guides to Reconstructing Continents

If this is so, three different guides have been proposed for fitting together the opposite sides of the Atlantic Ocean. The first method is well known and was used by A. Wegener, A. L. Du Toit and E. C. Bullard, J. E. Everett and A. G. Smith<sup>5</sup>. It depends on fitting the topography and matching the geology of opposite coasts. In Figs. 1 and 2 this is illustrated diagrammatically by the fit in shape of regions A and A'.

A second proposal<sup>6</sup> pointed out that, where a pair of aseismic ridges lead from an active volcanic island on the mid-ocean ridge to opposite coasts, the ridges join the coasts at conjugate points. For example, the Walvis and Rio Grande aseismic ridges join Tristan da Cunha Island to conjugate points on the coasts of Africa and South America. The ridges from Iceland to Greenland and Europe are another example. In Figs. 1 and 2 this case is illustrated by the lines Bb and bB'.

The third method suggested that at least some great submarine fracture zones are transform faults and that their ends join conjugate points<sup>1</sup>. In Figs. 1 and 2 this is illustrated by the transform fault and fracture zone C c c' O'.

In the South Atlantic all three methods lead to the same result, but at first sight one aspect is puzzling. Both the aseismic ridges and the fracture zones are the loci of past motions of the crust, but they are not parallel. Since a crustal plate cannot move in two directions at once, this seems to imply a contradiction.

### Possible Origin of Aseismic Ridges

One possible explanation is that different motions have been recorded. The fracture zones represent the motion of the plates in the crust relative to one another with no reference to the deeper mantle. It has been suggested elsewhere<sup>6,7</sup> that the pairs of aseismic ridges perhaps represent the movements of two crustal plates relative to a source in the mantle. Thus the aseismic ridges are chains of volcanoes, now inactive, which grew at a single place on the mid-ocean ridge and were then carried away, some to one side, some to the other, by streaming motion.

Their creation has been presumably due to unusually large and continuing source of lava in the mantle beneath the mid-ocean ridge (for example, Iceland and Tristan).

This pushing away of older volcanoes from a continuing source on a central rift zone was essentially the explanation for the geology of Iceland arrived at by G. Bodvarsson and G. P. L. Walker<sup>8</sup> as a result of field mapping. This explanation may also be extended to include the pair of ridges from Iceland to Greenland and Europe. These ridges lie in the same line, although they get older in opposite directions, are normal to the mid-ocean ridge and are parallel to the De Geer fracture zone, a transform fault lying between Greenland, Spitzbergen and Norway<sup>1</sup>.

Fig. 1. Sketch map of the South Atlantic. A and A' are conjugate points which fit together. Bb and bB' are the Rio Grande and Walvis ridges and C c c' O' is a fracture zone.

Fig. 2. Three-dimensional diagram illustrating how the two crustal plates on either side of the South Atlantic may be moving relative to each other and to a layer 100 km or more deep within the mantle.

Fig. 3. Diagram showing how to cut and fold a cardboard and paper model to illustrate a fracture zone intersecting two lengths of mid-ocean ridge which are separating with the formation of new crust. —, Hinge to fold sides up, ---, hinge to fold sides down

Fig. 4. Diagram showing the relationship of aseismic ridges to fracture zones which they intersect. Note that of each pair one has to terminate at a fracture zone

This arrangement of features may be interpreted to mean that the directions of motion of two crustal plates and of flow in the underlying mantle are all parallel with each other and normal to the axis of the mid-ocean ridge.

In the South Atlantic, on the other hand, the aseismic ridges form a chevron and are not parallel with the fracture zones of the equatorial Atlantic as Figs. 1 and 2 show. This has been interpreted to mean that the crustal plates are not moving in the same direction as that part of the mantle in which the source of the volcano lies. Since no method is known for measuring the direction of flow in the mantle directly, this interpretation is hypothetical, but, as will be shown towards the end of this article, it is an interpretation capable of further development.

In Figs. 1 and 2 the fracture zone  $O c c' O'$  is considered to represent the loci of relative motion of two crustal plates, whereas the two aseismic ridges  $Bb$  and  $bB'$  each represent the loci of motion of one of the plates relative to the mantle beneath. The crustal plates are not considered to be bounded by the Mohorovičić discontinuity, but by a zone of mobility in the upper mantle.

#### Relationships between Aseismic Ridges and Fracture Zones

This led me to speculate on what might be expected to happen if, during their growth, a pair of aseismic ridges came to intersect a fracture zone. This is hard to visualize, and indeed most of us are unaccustomed to thinking of geology in terms of growing oceans and continental drift so that this introduces new and difficult ideas. Simple paper and cardboard models help, and the construction of one which enables the properties of ridge-ridge transform faults to be studied is shown in Fig. 3.

With the aid of such a model and that of Fig. 4 it can be appreciated that on intersecting a transform fault one of a pair of aseismic ridges (that one which intersects the active part of the fault) is immediately cut off and removed laterally away from the source. That aseismic ridge must therefore come to an abrupt end against

the fault. The other aseismic ridge of any pair is not moved laterally, but the central rift in the mid-ocean ridge is moved away from it. It is therefore uncertain whether this aseismic ridge will end on the fault or continue. If it continues it will no longer touch the mid-ocean rift but it will seem to start at a random point. Only this member of each pair should still be active.

Some of the chains of islands in the Pacific Ocean seem to meet well the patterns predicted for pairs of aseismic ridges intersected by fracture zones as is shown in Fig. 5. In part, this is copied from Figs. 5.7 and 6.6 in H. W. Menard's book<sup>8</sup>, which shows three straight and parallel chains of volcanic islands (the Nasos, Cocos and Tehuantepec Ridges) each intersecting and apparently terminating against a fracture zone. It is particularly significant that on the other side of the East Pacific Rise in an approximately mirror-image position to the Nasos Ridge lie the Austral, Society and Tuamotu-Gambier ridges. This suggests that many chains of islands in the Eastern Pacific which are parallel either with the Nasos aseismic ridge or the Tuamotu aseismic ridge are associated in origin with the East Pacific mid-ocean ridge and that the great east-west fracture zones are too. If this is so and if the theory of transform faults is correct, then some very specific relationships can be predicted that should hold between the East Pacific Ridge, fracture zones, aseismic ridges and the patterns of magnetic anomalies.

The East Pacific Ridge has been well described by H. W. Menard<sup>8</sup> and the following account owes much to him and especially to his Fig. 6.12. This has been redrawn and modified in Fig. 5, which shows the general shape of the ridge. The eastern margin and northern crest have been overridden by the Americas. H. H. Hess has given me much advice, especially about the western Pacific. It would be interesting to identify the remaining, western margin of this ridge and important for the present discussion.

#### The ICSU Line, Possible Margin of the East Pacific Ridge

Menard shows the western margin of the East Pacific Ridge crossing the Pacific Basin. This margin should surely be discernible and, in seeking to identify it, other known rift margins provide the best possible guide. Heezen and Ewing<sup>10</sup> have implied that the Lomonosov Ridge is such a submarine margin. It may be partly volcanic according to Gakkell and partly sedimentary according to Ostenso. Elsewhere the Atlantic is bordered by continental blocks. Along the coasts are sporadic, large outpourings of basalt as in Greenland<sup>11</sup>. The only features which lie in the expected location in the Pacific Basin and which appear to have the required properties are, from north to south, the Emperor Seamounts, the group of very large seamounts at the north-western end of the Hawaiian chain, part of the western end of the Hawaiian Islands, part of the Mid-Pacific Mountains, the Line Islands Ridge and the eastern edge of the New Zealand submarine plateau. Between the last two features charting is inadequate, but a few elevations recorded as seamounts may represent crossings of a marginal ridge. No other group of features crossing the Pacific is so prominent.

Because many nations have contributed to knowledge of this feature and because great progress in oceanography resulted from the International Geophysical Year, it is proposed to call this feature the ICSU Line after the International Council of Scientific Unions which sponsored the International Geophysical Year.

#### Relationships of Ridges to Other Features

There has already been considerable debate about whether the fracture zones are genetically related to the

Island) with the north end of the Line Island ridge (near Johnston Island), but the distance cannot be precisely measured. According to this interpretation the Hawaiian Islands have a composite structure.

H. H. Hess assures me that there are offsets at the places where the Clarion and Clipperton fracture zones probably reach the Line Island ridge. They seem to have appropriate directions and lengths. The charting is too uncertain to draw any conclusions about fracture zones farther south. Again the displacements of the margin appear to agree well with theory.

(c) Transform faults should terminate against margins. The fracture zones become harder to trace beyond the ICSU Line, but the data are insufficient to make this a good test.

Fig. 6. Left, diagrammatic sketch of an unconstrained pattern of possible crustal and sub-crustal flow; right, the same for a pattern representing in simplified fashion the Earth's mid-ocean ridges, showing how the loop of ridge in the southern oceans could explain the directions of aseismic ridges, if the sources of their volcanoes lay below the crustal motions.

(d) All the aseismic ridges in the same crustal plate and on one side of a mid-ocean ridge should be parallel. On the east side of the East Pacific Ridge this is true of the Tehuantepec, Cocos and Nasca ridges and of the small companion ridge to the East (Nasca Two). On the west side it is true of the Gulf of Alaska Seamounts, the Hawaiian, Tuamotu-Gambier, Society and Austral Islands<sup>7</sup>.

(e) All the aseismic ridges should get younger from the margin towards the mid-ocean ridge with which they are connected, and so far as is known this is true of the East Pacific Ridge.

(f) Aseismic ridges should generally begin at a margin. The Hawaiian Tuamotu-Gambier, Society and Austral Islands all seem to start on or near the ICSU Line; the Marquesas do not and the older ends of others have been over-ridden.

(g) One should expect to find pairs of aseismic ridges symmetrically arranged in chevron pattern about the crest. The Tuamotu-Gambier, Society and Austral chains are so arranged relative to the Nasca and Nasca

Two ridges (to the extent that they have not been over-ridden).

(h) The theory predicts that in the Pacific aseismic ridges should terminate against the eastern end of dextral transform faults (that is, those which paradoxically show apparent sinistral offsets) and against the western end of sinistral faults. Aseismic ridges may cross and be active at the other ends of fracture zones. According to Menard<sup>8</sup>, the Mendocino, Pioneer, Molokai, Clipperton and Easter fracture zones show apparent sinistral offsets. As predicted the Tehuantepec, Nasca and Nasca Two ridges all stop against their eastern ends, and according to Hess<sup>10</sup> the Hawaiian Islands cross the western end of the Molokai fracture zone and are still active while the Austral Islands cross the Easter fracture zone.

For the other fracture zones the relationships should be the reverse, and it is true that the Galapagos Islands are still active, even if they scarcely cross the Galapagos zone. The Hawaiian Islands should not cross the Murray zone but appear to do so. This is the only exception, but may be due to a greater complexity in the structure of the Hawaiian chain than has heretofore been suspected.

The conclusion is that the fracture zones and aseismic ridges are associated with the East Pacific Ridge. The oldest rocks reported are Eocene in cores<sup>13</sup> and from Makatea Island in the Tuamotu group near the western margin<sup>10</sup>. Rapid spreading and rapid rates of sedimentation are indicated. The orientation of the aseismic ridges suggests that the floor of the Pacific is moving northwards like that of the Atlantic Ocean and several southern continents.

#### Possible Causes of Northward Spreading and Orientation of Aseismic Ridges

An explanation can readily be offered in terms of the possible sub-crustal currents mentioned earlier. On an infinite body they might flow as in Fig. 6 (left), but on a sphere they might be constrained to flow as in Fig. 6 (right). This pattern, like a J folded about the Earth, can be taken to be a diagrammatic simplification of the real mid-ocean ridge system and can be compared with Fig. 10 in my previous article<sup>1</sup>. The stem represents the Mid-Atlantic Ridge, the loop the mid-ocean ridge system through the Southern Ocean to the West Chile Ridge. Antarctica would be in the centre of the loop.

Because there is no sink within the looped source the diameter of the loop itself increases and the surface currents move outwards with twice the velocity of the deeper counter-currents. If the sources of volcanoes lie in the counter currents (if the convecting system is shallow), or within the stagnant cores of convection cells (if the system is deep), then the differential in rates of flow will produce chevron patterns in the aseismic ridges.

The northward motion is absorbed in the Alpine Himalayan and Circum-Pacific Mountains and hence has not affected the Icelandic ridges.

Besides Antarctica, another continent, Africa, is ringed by mid-ocean ridges on all but the northern side and corresponding effects can be detected in the Indian Ocean ridges.

I should like to acknowledge that this article could not have been written if the oceans had not been so well charted by others. I have particularly used maps by H. W. Menard<sup>8</sup> and H. H. Hess<sup>11</sup>, and a globe showing bathymetry<sup>12</sup>, but I first noticed the ICSU Line on a large new Soviet chart<sup>13</sup> which shows it clearly.

This article was written while I was a guest in the Departments of Geodesy and Geophysics and of Geology and in Churchill College, University of Cambridge; I thank them and particularly B. C. Browne, Sir Edward Bullard, H. H. Hess, M. N. Hill, R. G. Mason, D. H. Matthews and F. J. Vine for discussions which have been invaluable in arriving at these conclusions, though they

may not agree with all of them; and I also thank Sue Chappell and Sue Vine for their assistance.

## THE LONDON UNIVERSITY NUCLEAR REACTOR CONSORT

By Dr. P. J. GRANT

Department of Mechanical Engineering, City and Guilds College, Imperial College of Science and Technology, London, S.W. 1

ON June 22 the London University nuclear reactor *Consort* was formally opened by Lord Sherfield, chairman of the Governors of the Imperial College of Science and Technology and former chairman of the Atomic Energy Authority. The reactor was first made critical on April 9 and full power was reached on May 18. Commissioning was completed by the beginning of June.

*Consort* is a water-cooled and moderated reactor fuelled with enriched uranium (80 per cent <sup>235</sup>U) and has a power of 100 kW (thermal). It was designed jointly by the Nuclear Power group of Imperial College and by the General Electric Co., Ltd. The instrumentation was designed and supplied by Elliott Nuclears, Ltd., and the building, which was designed by W. S. Atkins and Partners, was constructed by W. E. Chivers and Sons. The whole project was financed by a grant from the Department of Scientific and Industrial Research (now the Science Research Council). The reactor has been constructed and is being operated by Imperial College on behalf of the University at the College Field Station at Silwood Park, near Ascot.

The University has also provided funds for a residential block of nine study-bedrooms for the use of those carrying out experiments at the reactor site.

The purpose of the reactor is to provide experimental facilities for research and training in nuclear engineering and applied nuclear science for the University and other educational institutions in the London area. *Consort* has therefore been designed to act as a source of neutrons for experimental purposes. The essential design feature of a neutron-source reactor is that the experimental facilities

should approach as closely as possible the reactor core so that the largest possible external fluxes are available for a given power.

Fig. 1 is a drawing of the general arrangement of the reactor, biological shield and experimental facilities. The reactor core consists of up to 24 fuel elements, each comprising twelve slightly curved plates of uranium-aluminium alloy clad in high-purity aluminium. The core is approximately 15 in. square by 24 in. high and is situated in a tank of water about 22 ft. deep and 3 ft. 9 in. in diameter; at the level of the core the tank is narrowed in one direction and has two flat faces where the distance between the core and tank is only 3.75 in. This water gap is provided to ensure nuclear decoupling of the core from any external assembly.

On one of the flat faces is constructed a hollow graphite thermal column to provide horizontal and vertical 'feeds' of thermal neutrons into large external assemblies and to provide spaces for the neutron irradiation of samples. On the other side is constructed the 'bare face' facility; this consists of a large space cut away in the fixed concrete of the biological shield with a short graphite section to lead the neutrons into it and to provide mechanical protection for the tank wall. In this space assemblies up to 4 ft. 6 in. wide and 9 ft. high can be placed.

In addition to these large irradiation facilities, twelve beam tubes are provided in which fluxes of between  $10^9$  and  $3 \times 10^{11}$  n/cm<sup>2</sup>/sec are available, and a small (1 in. diam.) tube is provided in the centre of the core in which a flux of  $2 \times 10^{13}$  n/cm<sup>2</sup>/sec can be obtained. If required, additional in-core irradiation space can be provided in one of the fuel-element positions.

Fig. 1. General arrangement of *Consort* reactor with dual-purpose thermal column. (By courtesy of General Electric Co., Ltd., England)

Fig. 2. Consort reactor under construction. (By courtesy of General Electric Co., Ltd., England)

Fig. 3. Consort reactor, general view on completion. (By courtesy of General Electric Co., Ltd., England)

Figs. 2 and 3 show general views of the reactor from the 'bare face' side during construction and after completion. Fig. 2 indicates that good use has been made of the possibilities for extraction of beams of neutrons.

Heat from the reactor core is removed by natural circulation of water within the tank. At 100 kW power the temperature rise of the water passing through the core is about 10° C. In order to maintain a steady temperature, up to 2,000 gallons per hour of water are extracted from the tank, passed through an air-cooled radiator in an adjoining plant room and returned to the bottom of

the tank. 10 per cent of the water flow is by-passed through an ion-exchange column to maintain a high water purity.

The reactor is controlled by four control rods. Three of these, two 'coarse' and one 'safety', are of cadmium clad in stainless steel and each has a reactivity worth of about 1.5 per cent; the fourth, the 'fine' rod, is of stainless steel and has a worth of 0.5 per cent. All the rods move vertically in aluminium shrouds occupying spaces between fuel elements.

The instrumentation for the control and safety of the reactor is conventional. It comprises a low-power pulse channel using a fission counter and logarithmic d.c., linear d.c. and two shut-down channels, all operating from ion chambers in the instrument thermal column. The circuits are arranged so that at least three nucleonic safety channels are in operation at any time; initiation of a trip sequence by any one of these shuts down the reactor. In addition to the nucleonic trips, the reactor is shut down by failure of any control rod mechanism to operate correctly and by any significant rise in the water temperature above its normal value. Besides the trip conditions, warnings are automatically given to the control room of nucleonic or physical failures which do not prejudice the safety of the reactor but which might prevent its proper operation.

The main reactor shield is of monolithic ordinary concrete except where it is cut away for the bare face and thermal column facilities. These are shielded by means of concrete blocks. In the vertical direction the core is shielded by about 11 ft. 6 in. of water, which is sufficient protection against gamma radiation from the core in the shut-down condition, and by two movable concrete slabs which are wheeled over the top of the reactor when it operates. Interlocks ensure that the shield doors are in position before the reactor can be made critical.

Normally, fuel need never be removed from the reactor tank. Fuel storage positions are provided at the bottom of the tank for fuel elements which are not required for a particular loading or if the core has to be dismantled so that access may be obtained to bare face facility without the necessity for working in the gamma-ray back-

Table 1. Consort Reactor Core Main Parameters

Power	100 kW
Fuel element	U.K.A.B.A. standard M.T.B. type
Plate material	U-Al alloy
Enrichment	80% <sup>235</sup> U
No. of plates per element	12
Wt. of <sup>235</sup> U per element (nominal)	138 g
Critical mass	3.045 kg (22.25 elements)
Core	
Operating mass	3.114 kg (22.75 elements)
Excess reactivity	0.54%
Moderator, coolant and reflector	Light water
Control rods and reactivity inserted	
Fine control rod	0.5%
Coarse control rods (2)	1.5% each
Safety rod (1)	1.5%

Table 2

Facility	Dimensions	Thermal neutron flux
'Bare face'	Flux available over area 3 ft. square. Space for erection of assemblies: 4 ft. 6 in. wide x 9 ft. high	$5 \times 10^{12}$
Dual-purpose thermal column	Horizontal and vertical 'feeds' of neutrons over areas 3 ft. x 3 ft.	$10^9$
Thermal column irradiation holes	Internal irradiation cavity: 6 ft. x 1 ft. 9 in. x 1 ft. 9 in. Five holes 3 in. square. One hole 7 in. square. All 3 ft. long	$5 \times 10^9$
Through tube	Passes through fixed graphite near tank	$5.5 \times 10^{12}$
Beam tube terminating in cave in shield	Three in. diameter hole in graphite near tank leads to cave 2 ft. 6 in. cube	$3.5 \times 10^{12}$ at input end
Beam tubes (9)	All 6 in. internal diameter at narrowest point. Increasing to 8 in. diameter at step half-way along length	$3 \times 10^{11}$ (3 tubes), $3 \times 10^9$ (6 tubes)
Vertical tube in centre of core	One in. internal diameter	$2 \times 10^{12}$
Vertical tube terminating in graphite near tank	5.8 in. internal diameter	$3.5 \times 10^{12}$

ground from the shut-down core. Fuel handling is carried out by means of a simple hand-operated tool under direct visual control.

Table 1 lists the main reactor parameters and Table 2 summarizes the fluxes available in the experimental facilities.

It is expected that about 75 per cent of the reactor operating time will be allotted to research and the remainder to postgraduate and undergraduate teaching. The initial demand for experimental time for research has been heavier than expected. About fifteen proposals have

already been authorized by the Reactor Safety Committee and nearly half of these are large-scale experiments requiring prolonged use of the reactor. Two short experiments were completed during the commissioning period. So far, the majority of the experiments have been put forward by Imperial College staff, who have been in closer contact with reactor progress than other potential users, but general demand is expected to grow rapidly now that routine operation has begun. It is clear that the reactor is meeting a real need, and we look forward to a long and useful operating life.

## OBITUARIES

### Sir John Gaddum, F.R.S.

THE death, on June 30, 1965, of Sir John Gaddum has deprived physiology and pharmacology of one of their leading personalities. He died after a long illness, uncomplainingly borne, at his home in Cambridge at the age of sixty-five. Born in Bowdon, Cheshire, he was educated at Rugby and at Trinity College, Cambridge. There he read mathematics and, in his last two years, physiology as part of the Natural Sciences Tripos. It was later a source of merriment to him and of solace to his fellow sufferers that he only gained a 'second class' in physiology. From Cambridge he went to University College Hospital, London, where he obtained his medical qualifications in 1925. For the next two years he worked with J. W. Trevan at the Welloome Physiological Research Laboratories in Beckenham.

Gaddum's first paper there on the antagonism of adrenaline and ergotamine on the uterus of the rabbit was an indicator of things to come: his interest in drug antagonism, his mathematical treatment of biological data, the use of smooth muscle as a convenient quantitative measure of drug action, were indicative of much of his later work. The years 1927-34 were spent at the National Institute for Medical Research, Hampstead, under the directorship of H. H. (now Sir Henry) Dale. Many of the papers of these years are exercises in quantitative pharmacology and have helped to lay the foundation of accurate measurement of drug effects, and of estimation of errors due to sampling and other sources. He introduced the 'normal equivalent deviation' in the evaluation of quantal assays. He devised or improved the biological assay of substances which occurred in tissues in such small quantities that their chemical determination was impossible. There was also the discovery, with U. S. v. Euler, of a biologically active polypeptide in tissues ('substance P'), and with H. Schild, of a fluorimetric test for adrenaline. However, the investigation he most enjoyed during this period was one which led to the discovery, with W. Feldberg, that acetylcholine was the chemical transmitter at preganglionic autonomic synapses.

During his stay at Hampstead, Gaddum married a former fellow student, Dr. Iris Mary Harmer, with whom he shared many interests during their long married life, and who now survives him. They had three daughters, all of whom are married.

During 1934-58 Gaddum held chairs in pharmacology in the University of Cairo, University College, London, the College of the Pharmaceutical Society of Great Britain, and Edinburgh. Here he succeeded A. J. Clark in 1942 after several war years spent in work for the Ministry of Supply, to which he remained an adviser for many years to come. The release of histamine, the nature of the transmitter at adrenergic nerve endings, the role of 5-hydroxytryptamine in brain activity, and the assay of bradykinin were among his interests in the Edinburgh years. In two papers he drew attention to the fact that many biological phenomena exhibit a lognormal

distribution. He greatly improved the specificity of biological assays. This was done either by the use of specific antagonists, if necessary by desensitizing the tissue with a large dose of the substance the presence of which was suspected; or unambiguous clues to the identity of the unknown material were obtained by measuring its effect on many organs in parallel and estimating its potencies in relation to known reference substances. To the end of his life, Gaddum worked on active substances extractable from tissues, but his interest shifted increasingly to the search for new transmitters in the central nervous system. His last paper, started before he became ill and completed during the years of illness, deals with the chemical and structural requisites of central nervous activity. It is now in the press. In 1958, Gaddum accepted an offer from the Agricultural Research Council to succeed I. de Burgh Daly as director of the Council's Institute of Animal Physiology at Babraham, Cambridge. Always ready for new experience, he took up the challenge of learning about the needs of the physiology of farm animals and travelled all over the world to find out what was done in this field elsewhere. The growth of the Institute during his directorship is a telling tribute to his success.

Gaddum's singular achievements were due to a combination of mathematical ability, technical inventiveness (he constructed many useful research tools, the last one, the 'push-pull cannula', in 1961), with an unflinching interest in all biological, in fact all natural, phenomena, of which physiology and pharmacology were but one section. He had the mind of a naturalist, looking for plants and birds on his travels, and possessed an intellectual curiosity which did not fail him to the end. The capacity to take interest in new disciplines stood him in good stead when he gave up his chair to become director of the Babraham Institute.

During the years that Gaddum held professorships he had pupils from many lands. These will remember not only his brilliant mind but also his complete lack of prejudice, his willingness to hear all views, his integrity and sense of duty, his kindness and modesty, and the way in which a busy man gave freely of his time to their many needs. Gaddum considered it a scientist's duty to encourage international co-operation, and he certainly made an outstanding ambassador of good will.

Among the honours conferred on him was the fellowship of the Royal Society in 1945, an honorary LL.D. from the University of Edinburgh in 1964, and a knighthood in the same year.

MARTHE VOGT

### Dr. H. J. Gough, C.B., M.B.E., F.R.S.

AFTER a working life devoted to research in engineering at the National Physical Laboratory, the War Office, the Ministry of Supply and Unilever, Ltd., Dr. H. J. Gough for the past ten years had been living in retirement at Rottingdean; but he had maintained his interest in his old pursuits and during his retirement had continued to

serve on several boards and committees. He died on June 1.

Gough will chiefly be remembered for his pioneer investigations into the mechanism of the fatigue of metals. On joining the staff of the Engineering Department at the National Physical Laboratory in 1913, Gough began his investigation of fatigue under the tutelage of Stanton and Barstow. He soon made the subject his own, and after service with the Royal Engineers throughout the First World War (in which he gained promotion from the ranks in the field and was twice mentioned in dispatches) he returned to the National Physical Laboratory to continue his research. His book on *The Fatigue of Metals* was published in 1924, and this book, with the book by Moore and Kommers published about the same time, remain the basic references on this subject. In the 1920's, Gough, with Hanson of the Metallurgy Department at the National Physical Laboratory, began to investigate the process of fatigue in single crystals of metals. In crystals of aluminium he demonstrated that under all stress conditions, including alternating torsional stresses, plastic deformation occurred by slip on the slip planes and in the slip directions subjected to maximum ranges of shear stress, and he showed that fatigue cracks developed at the points of maximum resolved shear stress and in regions of heavy bands of massed slip. Afterwards, by tests on single crystals of zinc, silver, antimony, bismuth and iron, they demonstrated the importance of slip as a precursor of fatigue cracking in all the truly ductile metals, and also made observations on deformation twinning and cleavage. By comparative tests on pieces containing one or two large crystals, Gough demonstrated that the intercrystalline boundary played no essential part in the fatigue process: the fatigue crack still developed within the crystal grains, and in extending it neither avoided nor sought out the crystal boundaries.

In 1930 Gough succeeded Sir Thomas Stanton as superintendent of the Engineering Division, and the consequent increase in his administrative duties compelled him to delegate much of the further prosecution of his researches to his junior colleagues; but he continued to play an active part in investigations into corrosion fatigue, fatigue under combined stresses, fretting corrosion and study by X-rays of the nature of fatigue damage.

In 1938 Gough was called to the War Office as director of scientific research; and in 1942 he was awarded the C.B. and became director-general of research and development, Ministry of Supply. Of the many contributions Gough made to the war effort, most were not, of course brought to public notice, but the system developed under his guidance for rendering innocuous unexploded bombs earned the gratitude of us all.

After the War, Gough became engineer-in-chief to Unilever, Ltd., and was responsible for building up the Engineering Department of the Company's advisory technical division in London and for co-ordinating engineers' activities through the organization at home and abroad. The work he did in these fields established the importance of good engineering and did much to improve the status of the engineer.

Gough was elected to fellowship of the Royal Society in 1933 and was president of the Institution of Mechanical Engineers in 1949. During the period 1945-50 he played a large part in the establishment of the Mechanical Engineering Research Laboratory and in the transfer of research in engineering from the National Physical Laboratory to that establishment (now the National Engineering Laboratory). In the formative years of the National Engineering Laboratory, Gough acted as chairman of the Committee which supervised research there into all matters relating to strength of materials, and he took an active part in the organization of the conference on fatigue of metals held at the Institution of Mechanical Engineers in co-operation with the American Society of Mechanical Engineers in 1956.

H. L. COX

Prof. D. S. Hendrie

PROF. D. S. HENDRIE's death at the early age of fifty-six when he was at the height of his powers and when assuredly a great future lay ahead of him was a severe blow to Scottish agriculture. One could feel the acute sense of depression that settled over his College when the news came through. Although a man of immense ability, he had a most becoming modesty and the rare gift of making even the most junior lecturer feel important. His door was ever open to all callers and he was a ready listener to new ideas. He was at his happiest when mixing socially with his staff and students and he was a great champion of students' rights and privileges.

In 1954 Donald Hendrie was appointed principal of the West of Scotland Agricultural College and first professor of agriculture in the University of Glasgow. He brought with him a freshness of approach stemming, no doubt, from the five years he spent in New Zealand, where he was agricultural adviser to the High Commissioner for the United Kingdom. He was, in a real sense, coming home, for he had been a distinguished scholar at both of the institutions where he was now to play a leading part. He graduated B.Sc. with first-class honours in agricultural economics at Glasgow, winning many prizes and attaining the highest aggregate mark in the examinations for the National Diploma of Agriculture. He also held a B.Sc. in estate management of the University of London and a diploma in agricultural science of the University of Cambridge. As recipient of a Ministry of Agriculture scholarship, he spent a year at the Ontario Agricultural College, Canada. From 1932 until he went to New Zealand in 1949 he held a succession of posts, first as lecturer in the West College and then in Yorkshire with the Ministry of Agriculture.

It is a tribute to Prof. Hendrie's remarkable versatility and adaptability that he was as well thought of by the farmers of South-West Scotland as he was by the highest academics of the universities. He was as much at home in the fields of his native Ayrshire as he was in the classrooms and laboratories, but it was as a committee man and as an administrator that he was supreme.

The memoranda which flowed regularly from his pen were models of clarity, and they produced results. The complex interrelationships between university and college were a challenge to his abilities; they were soon sorted into satisfactory orderliness. It was also no easy matter to administer a College that existed in two parts separated by thirty miles, but under Prof. Hendrie's guidance the fusion was complete.

His talents were early recognized and he was asked to advise on the setting up of Faculties of Agriculture in two universities in Africa. He was a Governor of the Scottish Horticultural Research Institute, and of the Grassland Research Institute, Hurley. The many committees on which he served are too numerous to mention, but among the more important were the Scottish Milk Records Association, the Blackface Sheep Breeders Association, the Agricultural Research Council Standing Committee on Research Affecting Plants and Soils, the Livestock Records Bureau, and the West of Scotland Conservancy of the Forestry Commission. He was a member of the Government committee of enquiry into grassland farming of the Secretary of State's Scottish Agricultural Improvement Council, and chairman of its grassland committee.

He forged close links with industry, recognizing the important part that chemical firms have played and are playing in the development of agriculture.

In fine, we could ill afford to lose such a man, but we have cause to remember with gratitude his wisdom in developing agriculture in this area and his influence in wider spheres. He was a strong family man. In all his work he was aided and encouraged by his wife Jenny, and he leaves a son who is at present studying agriculture.

W. FLETCHER

## Prof. Jacques Bourcart

THE death of Jacques Bourcart on June 24 at the age of seventy-three removed from the scene of marine science in France a man whose richly varied life embraced very much more than great and successful activity applied in his own field of marine geology.

Bourcart was a patriot of patriots and it was doubtless the extraordinarily robust life which he led in both World Wars, inclusive of remarkable service in the Resistance, that made of him the man who became established as 'Patron' in the affections of his numerous students at the Sorbonne. It was in the field that Bourcart particularly excelled, and his detailed acquaintance with the geology of Morocco and Albania gave him that wide sweep of knowledge which drew so many admirable young people into his line of work. It was as an 'animator' of students that Jacques Bourcart won special fame. Conversation with him was not only rewarding and enjoyable; it was exhilarating—so buoyant and enthusiastic was he when engaged on some topic such as his well-known theory of continental flexure! This theory, which held that shorewards of a certain submerged zone elevation had taken place whereas seawards subsidence had occurred, was first announced in 1926 as a result of his detailed studies of the Moroccan littoral regions. It was indeed a good thing that Joubin did when he drew Bourcart into oceanography. The theory of continental flexure was applied to elucidate many puzzling changes of sea-level in the geological past.

Bourcart's thesis for his doctorate in science (1922) dealt mainly with the geology and geography of Albania, but it was in character that it strayed a good deal into discussions of the Albanian people and their language. In 1925 he was director of research in dynamical geology at the Sorbonne, and, with the passage of the years, he turned increasingly to littoral and submarine geology with particular attention to deep-sea sedimentation and bottom topography. His knowledge of Arabic led to service in Lebanon and Syria in the early days of the Second World War, but a later stage in that conflict saw him applying his vast knowledge of coastal bathymetry and morphology to the benefit of the allied forces. After remarkable military services which gained him great honour, Bourcart was appointed full professor at the Sorbonne in 1950. Five years later came the crowning of his university career when he became professor of physical geography and dynamical geology in succession to Prof. Lutaud. In this post he remained until he reached the age limit in 1961.

Bourcart was the first in France to have recognized the scientific importance of, and to have foreseen a great future for studies of, sea-bed geology and especially of abyssal sediments. He was a prolific writer and to him is due a fine set of bathymetric charts of the Mediterranean

which delineate those remarkable canyons which he had studied in detail, but the nature of which had been kept veiled in secrecy during the Second World War.

It was typical of Bourcart that, when a fund was raised to present him with the usual sword on his election to the Academy, he chose that the subscriptions should endow an academic prize able to pay the travelling expenses of a meritorious student wishing to pursue some study in physical oceanography.

In his later years Bourcart found it possible to extend the range of his busy life enough to include bathyscape descents and trips in the 'Diving Saucer'. The death of such a man will be felt far beyond the confines of his own country which he served so devotedly alike in the field of science and on the field of battle. J. N. CARBUTHERS

## B. M. Kupletsky

BORIS MIKHAILOVICH KUPLETSKY, a prominent Soviet petrologist, died on January 14 at the age of seventy-one. Kupletsky is best known as the pioneer investigator of the Kola Peninsula igneous alkaline complexes. He began his strenuous field work as a member of A. E. Fersman's 'heroic team' in 1920. From 1920 until 1930 he was an assistant of F. Y. Loewinson-Lessing in the Leningrad Polytechnical Institute. His most important works on the rocks of the Kola Peninsula are: "Petrography of the Khibina Tundra" (1926) and "Petrography of the Kola Peninsula" (1932). Besides descriptive petrology, Kupletsky published very important works dealing with the classification and genesis of various igneous rocks. These are: "Nepheline Rocks" (with T. M. Oknova, 1934); "Genesis of Alkaline Rocks" (1936); "Nepheline Syenites in the U.S.S.R." (1937); "Classification of Granitoids" (1939); "Classification of Lamprophyres" (1944).

S. I. TOMKHEFF

## A. A. Saukov

ALEXANDER ALEXANDROVICH SAUKOV, a prominent Soviet geochemist, died in Moscow on October 23, 1964. He was born on August 15, 1902, and studied under F. Y. Loewinson-Lessing and D. S. Belyankin in the Leningrad Polytechnical Institute, from which he graduated in 1929. He began his research on the geochemistry of mercury under the guidance of A. E. Fersman. Besides numerous papers on various geochemical topics, Saukov published an excellent text-book entitled *Geochemistry* (first edition, 1950; second edition, 1952), which gained a German translation (*Geochemie*, 1953). His second book bore the title *Geochemical Methods of Prospecting for Mineral Deposits* (1963). In 1961 Saukov came to Britain at the invitation of the Royal Society of London and lectured at a number of universities.

S. I. TOMKHEFF

## NEWS and VIEWS

## C.S.I.R.O. Division of Biochemistry and General Nutrition: Dr. A. T. Dick, O.B.E.

DR. A. T. DICK has been appointed chief of the Division of Biochemistry and General Nutrition of the Commonwealth Scientific and Industrial Research Organization of Australia. Dr. Dick succeeds Dr. H. R. Marston, who relinquishes his post at the end of August (*Nature*, 207, 465; 1965). He joined the Division of Animal Health as a research officer in 1933 and took up duties with Dr. A. W. Turner at Townsville, Queensland. There he applied his knowledge of chemistry and microbiology to some of the animal health problems of the region. In 1936 he joined Dr. Turner at the Parkville regional laboratory of the Division of Animal Health and Nutrition,

where he continued his microbiological studies of the causal organism of bovine contagious pleuropneumonia. Later in 1936 he took up work on chronic copper poisoning in sheep and in 1938 this was extended in a co-operative investigation of so-called toxæmic jaundice of sheep, which proved to be a pyrrolizidine alkaloidosis due to the consumption of *Heliotropium europæum*. The disease frequently became manifest as a hepatogenous chronic copper poisoning. This led to studies of copper metabolism in the sheep, and he demonstrated for the first time the interactions between molybdenum, inorganic sulphate and copper. He has continued experimental work on the toxic action of the pyrrolizidine alkaloids and on copper metabolism. He graduated B.Sc. with honours in 1932, M.Sc. in 1938, and D.Sc. in 1954 from

the University of Melbourne. He shared the David Syme Research Prize of the University of Melbourne in 1954, was elected a Fellow of the Royal Australian Chemical Institute in 1952 and a Fellow of the Australian Academy of Science in 1964. He was appointed an Officer of the Order of the British Empire in 1965 and in the same year he was awarded a senior foreign scientist fellowship by the National Science Foundation to work at the University of Missouri which he will take up in 1966. He has held various offices with the Royal Australian Chemical Institute, the Institute of Medical Laboratory Technology and the Victorian Society of Pathology and Experimental Medicine.

#### Statistics in the University of Edinburgh:

Prof. D. J. Finney, F.R.S.

PROF. D. J. FINNEY has been appointed to the newly instituted chair of statistics in the University of Edinburgh as from September 1966. Prof. Finney, who is well known for his work in statistics, is at present professor of statistics in the University of Aberdeen. He was born in Lancashire and educated at Lymm and Manchester Grammar Schools before obtaining an Open Scholarship at Clare College, Cambridge, where he graduated in mathematics in 1937. He took his M.A. in 1941, and a D.Sc. at Cambridge in 1947. After two years' research at Cambridge and London, he was from 1939 until 1945 assistant statistician at Rothamsted Experimental Station and, from 1945 until 1954, lecturer in the design and analysis of scientific equipment at the University of Oxford. In 1954 he moved to Aberdeen as reader in statistics, and director of the Agricultural Research Council Unit of Statistics. He was appointed to the chair of statistics in Aberdeen in 1963. In addition he has acted as consultant statistician to numerous institutions; he was visiting professor at the University of North Carolina in 1949, and at Harvard in 1962-63. Since 1961 he has been honorary director of the Research Group in Biometric Medicine of the Scottish Hospitals Endowments Research Trust, and since 1963 a member of the Adverse Reactions Sub-Committee of the Committee on the Safety of Drugs. He is a vice-president and past-president of the Biometric Society, a former vice-president of the Royal Statistical Society, and a member of numerous other societies in the fields of statistics and genetics. Although originally a mathematician, Prof. Finney is primarily interested in the application of statistical methods to biology, including agriculture and medicine. His research has been particularly concerned with statistical estimation, biological assay, experimental design, human genetics, screening and selection, and forest sampling.

#### Bland-Sutton Institute of Pathology:

Prof. R. W. Scarff

PROF. R. W. SCARFF, who retires this month, has for the past seventeen years been director of the Bland-Sutton Institute of Pathology at the Middlesex Hospital Medical School and responsible for all the teaching, research and routine hospital pathological investigations carried out there. Himself a student of the Middlesex, he joined the staff of the Bland-Sutton Institute in 1924 shortly after qualifying. The title of professor of morbid anatomy and histology was conferred on him in 1946, and two years later he succeeded Prof. J. McIntosh as director and professor of pathology. The Bland-Sutton has always had a reputation for cancer research, and Prof. Scarff has done much to enhance this. He has for long been closely connected with the British Empire Cancer Campaign for Research, having been appointed secretary of its Scientific Advisory Committee in 1935, a post he held until 1954 when he became honorary secretary. Nearly twenty years ago, sensing the need

for a new publication to deal with the rapidly increasing number of papers on cancer research, he started, and became editor of, the *British Journal of Cancer*, under the auspices of the British Empire Cancer Campaign for Research. This new *Journal* he developed along the same lines as the *British Journal of Experimental Pathology*, which he was already editing at that time. A highlight in his career was the 1958 International Cancer Congress held in London, for the great success of which he was, as secretary-general, largely responsible. Prof. Scarff's personal research work has covered a variety of subjects through the years, but has mainly been connected with malignant disease, and in 1958 he was appointed head of a World Health Organization International Reference Centre for the study of mammary tumours. Since 1960 he has been consultant adviser in pathology to the Ministry of Health, while among his increasing international activities has been his appointment as secretary and treasurer of the International Council of Societies of Pathology, in the formation of which body he played a leading part.

Prof. G. Dick

PROF. G. DICK has been appointed to succeed Prof. R. W. Scarff as from April 1, 1966. Prof. Dick will direct the Bland-Sutton Institute and head the Department of Medical Microbiology. After graduating M.B., Ch.B. at the University of Edinburgh in 1938 and B.Sc. with first-class honours in pathology in 1939, he served as pathologist in the Royal Army Medical Corps in Africa during the Second World War. In 1946 he joined the Colonial Medical Research Service and worked in Uganda on the natural history of yellow fever and other arboviruses. He was awarded a Rockefeller Foundation fellowship in 1948 and worked in New York and Baltimore on the relationship of Mengo virus to encephalomyocarditis virus and on methods of preparing inactivated poliovirus vaccines. In 1949 he graduated M.P.H. at Johns Hopkins University. In 1951 he became a member of the scientific staff of the Medical Research Council and worked at Mill Hill on the aetiology of mouse hepatitis. Since 1955 he has held the chair of microbiology at the Queen's University, Belfast. During this period he has worked on the development and evaluation of poliovirus vaccines. He has served on several Medical Research Council and Ministry of Health committees concerned with problems of immunization against virus diseases. Prof. Dick graduated M.D. in 1949 and D.Sc. in 1958. He was awarded the Singapore Gold Medal on both occasions. He was admitted M.R.C.P.(Edin.) in 1953 and elected Fellow in 1955, and was admitted M.R.C.P.(Lond.) in 1960 and F.C.Path. in 1964.

#### Zoology and Comparative Physiology in the University of Birmingham:

Prof. L. H. Finlayson

DR. L. H. FINLAYSON, senior lecturer in the Department of Zoology and Comparative Physiology in the University of Birmingham, has been appointed to the second chair in the Department of Zoology and Comparative Physiology in that University. Dr. Finlayson was educated at Kilmarnock Academy and the University of Glasgow, where he obtained a first-class honours degree in zoology in 1945. Having served for a year in the Pest Infestation Laboratory at Slough, he was appointed to the staff of the Department of Zoology at Birmingham, where he became senior lecturer in 1960. In 1952-53 he held a Rockefeller Foundation fellowship at Harvard, and in 1964-65 he was temporarily seconded to the Medical School of the University College of Southern Rhodesia and Nyasaland to fill the place of reader in biological sciences. Dr. Finlayson has worked in various fields of experimental entomology and is internationally known for his work on the fate of certain insect muscles during metamorphosis

and on stretch receptors associated with the insect body-musculature. During his stay in Africa, Dr. Finlayson opened up new aspects of research into the metamorphosis of the tsetse fly. In the field of higher education he took an active part in the modernization of biological teaching both in the grammar school and in the university. The new biology building at Birmingham owes much to his untiring participation in its planning and equipping.

#### Royal Armament Research and Development Establishment: Dr. R. H. Barker

DR. RONALD BARKER has been appointed the second deputy director of the Royal Armament Research and Development Establishment. Born in Dublin in 1915, Dr. Barker was educated at University College, Hull, where he obtained the London B.Sc. honours degree in physics in 1938. He was awarded a Ph.D. in 1945 for research on digital servo systems. Dr. Barker started his career with the Standard Telephone and Cable Co., at Woolwich, with whom he spent three years. In 1941 he entered the Civil Service, and joined the Signals Research and Development Establishment of the Ministry of Supply, where he was promoted to senior principal scientific officer in 1954. His interests there included the digital transmission of fire-control data and telemetry for guided weapons. In 1954 he attended the thirteenth course at the Joint Services Staff College and, on completion of this course, he was appointed assistant director electronics research and development (air) at the Ministry of Supply headquarters, with special responsibility for airborne radar, air communications and navigation aids. In 1957 he returned to the Signals Research and Development Establishment as superintendent of research. He left the Civil Service in 1959 to become deputy director of the Central Electricity Generating Board's laboratory at Leatherhead, where he remained for two years. In 1961 he joined the board of R. B. Pullin and Co., Ltd., which later became part of the Rank Organization, and it was from this firm that he rejoined the Scientific Civil Service to take up his present post. In his new appointment, Dr. Barker has direct responsibility for two Divisions of the Establishment dealing respectively with basic techniques and the applications of explosives.

#### Physics in the University of Manchester:

Prof. P. G. Murphy

DR. P. G. MURPHY, who has been appointed to the newly established additional chair of physics at the University of Manchester, is at present a senior member of the research staff of the Rutherford High Energy Laboratory at Chilton, Berkshire. A Cambridge graduate, Dr. Murphy gained his Ph.D. at the University of Chicago, where he studied problems in atomic and nuclear physics under Prof. S. K. Allison. He was for several years an I.C.I. Fellow in the University of Liverpool, working with Prof. J. M. Cassels in high-energy physics research at the 156-in. synchrocyclotron. In 1960 he took a fixed-term research appointment at the Rutherford Laboratory, and spent the next eighteen months on detached duty at the University of California at Berkeley, where he carried out several experiments at the 6-GeV Bevatron accelerator as a member of the group led by Drs. E. J. Lofgren, B. Cork and W. A. Wenzel. This group developed the first spark chamber to be used in a high-energy physics experiment, and studied  $K$ -meson scattering, and polarization effects in  $\pi$ -meson scattering and in  $\Lambda$  and  $\Sigma^+$  hyperon decays. Since the autumn of 1961 Dr. Murphy has worked in the *Nimrod* research programme, as joint leader of the resident counter group. He and his colleagues have completed experiments at *Nimrod* on the scattering of  $\pi^+$  and  $\pi^-$  mesons by liquid hydrogen and by a polarized proton target which they and Dr. H. H. Atkinson developed. He gave a course of lectures at the University of Reading on symmetry

properties in elementary particle physics. He was promoted to senior principal scientist in 1964.

#### Physical Chemistry in the University College of Swansea: Prof. J. H. Purnell

DR. J. H. PURNELL, at present lecturer in physical chemistry in the University of Cambridge, and a Fellow of Trinity Hall, has been appointed to the newly established chair of physical chemistry in the University College of Swansea. He will therefore be returning to South Wales, of which he is a native, having taken his first degree at the University College of Cardiff in 1946. Following this he was successively assistant lecturer and lecturer at Cardiff, during which period he was awarded the Ph.D. degree of the University of Wales. In 1952 he migrated to Cambridge in order to work with Prof. R. G. W. Norrish; there he obtained a second Ph.D. in 1955. In the same year he was appointed demonstrator in physical chemistry at Cambridge, becoming lecturer in 1960; he became a Fellow of Trinity Hall in 1958. His work has been mainly concerned with the kinetics of pyrolysis of hydrocarbons and metal alkyls, and related processes such as inhibition. It has been distinguished by the application of gas chromatography to the analysis of products, which has made possible a more detailed and deeper insight into the mechanisms of reactions than was possible previously. Dr. Purnell's interest in gas chromatography has resulted in his becoming a pioneer not only in its application but also in the understanding of the basic physical chemistry of the technique. It has led him into thermodynamic considerations and the extension of the general techniques to solution and adsorption studies, liquid surface properties and the measurement of molecular weights. He is the author of a distinguished monograph on the subject of gas chromatography. At present he has an active school of research at Cambridge with interests in photolysis at low temperatures, the pyrolysis of olefines, and the simulation of complex chemical reactions by computer techniques. He may be expected to pursue these lines of work, among others, at Swansea.

#### British Electrical Power Convention

THE seventeenth British Electrical Power Convention was held at the Dome, Brighton, during June 21-24, 1965, and records of the proceedings have recently been made available by the press officer of the Electrical Development Association in London. The presidential address on "Electricity and Economic Policy" was delivered by Sir Ronald Edwards, chairman of the Electricity Council; his theme was the planning of the electricity supply industry to meet a maximum demand of 54,000 MW in 1970 (compared with 30,000 MW in 1964) and the economic and technical factors in such planning; he had much to say on competition in the field of fuel and power, particularly the future of the gas industry which "... will, as soon as it can, turn its back on coal and rebuild its future on oil and natural gas". The Citrine Lecture was presented by Lord Hinton of Bankside, former chairman of the Central Electricity Generating Board, and entitled "The Future of Power Technology"; he considered that future trends of technology in the energy industries depend on a combination of economic, social and commercial factors, remarking that "... the future of the coal industry depends on electricity and the future of gas is part of the future of the oil industry". On the subject of nuclear power, Lord Hinton said that it "... was certainly emerging from its expensive adolescence and should be able to compete commercially with conventional power in favourable conditions before 1975". "The Future of Gas" was the subject of a paper by Sir Henry Jones, chairman of the Gas Council; commenting on the comparative efficiency of gas and electricity production, he said that an engineer may still "question a system

which involves the loss at the power station in flue gases and cooling water of two-thirds of the heat in the fuel. The gas industry uses production processes in which roughly a tenth of the heat in the feedstock is used. Up to 92 per cent of the heat value in the raw material is available in the gas produced". Mr. John Davies, vice-chairman of Shell-Mex and B.P., Ltd., read a paper on "The Future of Oil" in which he prophesied that "Thirty years from now the U.K. will be using 200 million tons of petroleum compared with the 61 million tons of today". This was a paper of most exciting forecasts for the oil industry in the years ahead. The picture of the coal industry, as now phased and evolving, was presented by Lord Robens, chairman of the National Coal Board, in his paper on "The Future of Coal"; he said that there was great potential for increasing productivity in the coal industry; that the task of rationalization should be completed by 1970; and that a completely new approach to mining techniques, elimination of uneconomic capacity and increased output from profitable pits were among the modern developments to be reckoned with. "The goal of cheap and abundant supplies of electricity for British homes . . . to be achieved much sooner than most people thought" was the subject of a joint paper "Electricity's Future in the Home—The Complete and Competitive Service" by E. G. Plucknett (Tube Investments, Ltd.) and S. F. Steward (British Electrical and Allied Manufacturers' Association).

### Engineering Manpower In Profile

AN intensive investigation of contemporary American engineering manpower, not without interest and significance in comparable disciplines in the United Kingdom, has resulted in a report from the National Engineers Register, based on responses to a detailed questionnaire sent to a cross-section of engineers in the United States by the Engineers Joint Council, made possible through a contract with the National Science Foundation, entitled *Engineering Manpower in Profile* (Pp. 30. New York: Engineers Joint Council, 345 East 47th Street, 1965. 1 dollar). More than 57,000 individuals representative of the membership of 41 leading engineering societies returned the required information, revealed by an exhaustive questionnaire (reproduced in this report). "The nation's engineer is a man, median age 41, who works in industry or is self-employed, and, though he leans towards electronics and work management, may be employed in any of 115 areas of technology. In addition, he and his fellow engineers tend to concentrate in New York and California." Among the pertinent findings of this survey, it is established that: about 71 per cent are employed in industry or self-employed; another 8 per cent work for educational and non-profit institutions; 15 per cent are employed by government; more than 1 out of every 5 engineers possess a doctorate or master's degree; only one-half of one per cent of responding engineers are women; about 42 per cent of the respondents are receiving some degree of support or sponsorship from Federal programmes; and the profession is characterized by its great variety of specialities. The survey has further demonstrated that there is a growing realization that engineering is "... the vital element in translating far-ranging scientific discoveries into practical use". This report provides the factual information latterly demanded by industries, educational institutions and Congressional groups in the United States and it is certain to provide a strong basis for guiding and executing many plans and projects now in contemplation in the engineering field in that country.

### German Aid to Developing Countries

THE Overseas Development Institute has published a survey of the sources, policy and structure of German aid to developing countries, aimed at promoting economic

development in those countries (*German Aid: a Survey of the Sources, Policy and Structure of German Aid*. By John White. Pp. 221. London: The Overseas Development Institute, Ltd., 1965. 20s.). Successive chapters of the survey describe the growth and volume of the aid programme, its administrative structure, sources of funds and general policy. Other chapters deal with classification and terminology, bilateral financial assistance, the relations between Germany and other donor countries, problems of private investment, trade, technical assistance in developing countries, and technical and academic programmes in Germany. There are two chapters dealing with technical assistance by non-Government organizations, and with public opinion in Germany. Of 920 German experts overseas on December 31, 1963, 81 were in Europe, 298 in Africa, 439 in Asia and 102 in Latin America. Of the 6,228 technical trainees financed from Federal or L nder funds up to December 31, 1963, 507 were from Europe, 3,277 from Africa north of the Sahara, 1,029 from Africa south of the Sahara, 289 from the Middle East, 414 from Southern Asia, 307 from the Far East, 113 from Latin America and 229 from South America. Of 5,649 Government-sponsored technical trainees up to September 30, 1963, 529 were senior staff, 3,505 engineers, 409 foremen and 1,206 skilled workmen. At the end of the summer term, 1963, there were 27,000 foreign students in Germany, including 18,000 from developing countries, out of a total student body of 370,000.

### Institute of Biology Examinations

THE Council of the Institute of Biology has approved proposals concerning the examination for membership (*Institute of Biology Journal*, 2, No. 4; 1964). Courses are designed to last for three years of part-time study and assume a Higher National Certificate in applied biology as the entry requirement. At the end of one year's study a Part 1 examination will be taken in the principal subject, a cognate subject and principles of biology. The remaining two years of the course will be devoted to the special subject, and lead to the Part 2 examination. The special subjects so far approved are biochemistry, entomology, microbiology, pharmacology and plant pathology. Courses are expected to commence in September 1965. It is also reported that, in the summer of 1964, examinations for the Ordinary Endorsed Certificate in Biology were held in 21 centres in England and Wales and Northern Ireland. There were 210 candidates, of whom 156 passed, 36 failed and 18 were referred in one subject. Ten students who had been referred in the Higher Endorsed Certificate in 1963 succeeded in passing the examination in 1964. The first examinations for the Higher National Certificate in Applied Biology were held at 12 colleges in England and Wales. There were 106 candidates, of whom 86 passed, 6 with distinction. One student was referred and 19 failed. In Scotland, courses for the Ordinary National Certificate were offered by five colleges: 83 candidates produced 58 passes, 19 failures and 6 referrals. Six students received distinction or special mention. Two colleges presented candidates for the Higher National Certificate. Of the 25 entrants, 17 passed, 3 failed and 5 were referred. Three students attempted to add a supplementary subject to their Higher National Certificate, but only one succeeded.

### Bee-keeping by John Evelyn

OVER many years John Evelyn (1620–1706) worked at a book treating every aspect of gardens and gardening, with the title *Elysium Britannicum*. At the time of his death this work was neither finished nor published and the manuscript has since lain in Christ Church, Oxford. One section of this manuscript, probably written in the 1680's, deals with bees and apiaries, and has now been reproduced in full, together with facsimiles of some of the

rough illustrations, in the journal of the Bee Research Association: *Bee World* (46, No. 2, 48; 1965). While this compilation does not add to our present knowledge of the honey-bee, it does contain much that is of interest, such as his clearly illustrated account of several types of sectional hives and how to use them, and a description of the "Transparent Hives" in the apiary of the "most ingenious Mr. Mewes". The wasteful methods of the housewife who kills the bees to get the honey are roundly condemned. An interpolation by another hand on "The Method to govern Bees" contains advice on which colonies to keep over the winter and which to destroy. This includes the sound physiological observation that "a poor or small swarm will require more feeding and tendance than a great swarm; the reason is, that a hive full of Bees keep a heat within which is nourishing; for the stomach requires least meat in hot weather". The dancing of the scout bees and the guiding of the colony to their new quarters are well described. A scout brings the tidings and gives notice "by a certain touch which he imparts to the out guards that by a kind of shivering motion communicate it to the whole swarm and centre bees in a moment"—which then disperse and fly immediately to the new home.

### Countryside In Wales

THE twentieth annual report of the Caernarvonshire Branch of the Council for the Protection of Rural Wales covers the year April 1964–March 1965 (Pp. 28. Bangor: H. W. Owen, Honorary Secretary, 202 High Street, 1965). While affirming the Council's belief that rightly sited and designed development is possible with acceptable loss to the landscape, the Council holds that a heavier toll than ever before has been taken during the year in Caernarvonshire, mainly through the 400-kV line across south Caernarvonshire. The Council is unimpressed by the purely economic argument of the Central Electricity Generating Board, and points out that on the Northern route of the 400-kV line the Board could still meet the wishes of the Council and of the County Planning Authority by taking a lower-sited line from Bwlch-y-Deufen and a shorter crossing of the Conway Valley, with certain existing cables placed underground. The Council shares the concern of the National Parks Commission as to the intrusion of mass recreational facilities and in all that is left of "Wilder Wales" urges that the emphasis should be on low-cost maintenance conservation. It also welcomes the "Operation Neptune" of the National Trust, and questions the Minister's decision to approve a new chalet town adjoining the sandhills at Morfa Bychan. It asks for priority in designating the Coed Helen Estate and the adjoining coastal area to Llandwrog as an 'Area of Outstanding Natural Beauty'.

### International Commission on Zoological Nomenclature

NOTICE is hereby given of the possible use by the International Commission on Zoological Nomenclature of its plenary powers in connexion with the following cases, full details of which will be found in the *Bulletin of Zoological Nomenclature* (22, Part 2; May 18, 1965): (1) Designation of a type-species for *Limacia* Müller, 1781 (Gastropoda). *Z.N.(S.)* 1665. (2) Designation of a type-species for *Leuctra* Stephens, 1835 (Insecta, Pleocoptera). *Z.N.(S.)* 1671. (3) Designation of a type-species for *Nupedia* Karl, 1930 (Insecta, Diptera). *Z.N.(S.)* 1691. (4) Designation of a type-species for *Heteroptrypa* Nicholson, 1879 (Bryozoa, Trepostomata). *Z.N.(S.)* 1693. (5) Designation of a type-species for *Peronopora* Nicholson, 1881 (Bryozoa, Trepostomata). *Z.N.(S.)* 1693. (6) Designation of a type-species for *Bastis* [Leach, 1815] (Insecta, Ephemeroptera). *Z.N.(S.)* 1620. (7) Suppression of the specific name *Ephemera bioculata* Linnaeus, 1758 (Insecta, Ephemeroptera). *Z.N.(S.)* 1620. Any zoologist who wishes to comment on any of the foregoing cases should

do so in writing to the Secretary, International Commission on Zoological Nomenclature, c/o British Museum (Natural History), Cromwell Road, London, S.W.7, before November 18, 1965.

### Mycobacterial Skin Ulcers

In the past two and a half years, 28 cases of mycobacterial skin ulcers have been seen and treated at the Medical Research Centre, Bulawayo. Drs. P. J. Barnard and L. Jacobson suggest (*Cent. Afr. J. Med.*, 11, No. 5; 1965) that this entity begins as a phlegmon in the subcutaneous tissues with peripheral spread causing pressure necrosis of overlying skin, thus forming an ulcer. The ulcer is associated with wide undermining of skin edges and induration of the surrounding skin. Diagnosis has been made by history and clinical appearance, by taking a smear from underneath the edges of the ulcer, and staining for acid-fast bacilli, and by biopsy of the ulcer edges, especially the gelatinous material. The only effective treatment has been wide excision of the involved tissue followed later by split-thickness skin grafts. Much remains to be done to determine the epidemiology of this disease. Some workers suggest that *Mycobacterium ulcerans* is a soil saprophyte; others feel that certain fish may act as a reservoir of infection.

### Venereal Infections

THE dramatic decline in the reported incidence of venereal syphilis and gonorrhoea in many countries between the late nineteen-forties and the early nineteen-fifties, following the introduction of penicillin and other antibiotics, was a landmark in the history of public health. Unfortunately, in both these diseases, a persistently rising incidence has been noted in many countries after an all-time low in and around the mid-nineteen-fifties. The reasons for this disturbing trend are analysed in a comprehensive report on the World Health Organization's programme in the endemic treponematoses and venereal diseases, originally submitted to the thirty-fourth session of the WHO Executive Board, in May 1964 (*International Work in Endemic Treponematoses and Venereal Infections, 1948–1963*. Pp. 47. Geneva: WHO; London: H.M.S.O., 1965. 2 Sw. francs; 3s. 6d.). It is stressed that the public health methods available for the control of venereal syphilis are as effective to-day as they were before the recrudescence of the disease became apparent in many countries a few years ago, but that there is an urgent need for a more determined application of present-day knowledge in public health programmes in this field. In gonorrhoea, on the other hand, there is increasing evidence of resistance to one or more of the antibiotics at present in use, though this is a localized rather than a general phenomenon. The chief difficulty is that of bringing cases and contacts to treatment quickly enough to overtake the rapid spread of the infection in the community, and it seems unlikely that the disease can ultimately be controlled except by mass treatment or some form of immunoprophylaxis. In the endemic treponematoses of childhood, striking progress has been made—thanks in large part to the work of the World Health Organization in this field. In most countries where mass campaigns against these diseases have been carried out, the prevalence among rural populations has rapidly regressed to a fraction of 1 per cent. Some 50–60 million people, however, still live in areas of medium or low prevalence where no intensive effort has been made to control these diseases. It is also hoped that it will now be possible to accelerate their elimination in these areas by means of selective, multi-purpose, or integrated campaigns. In the light of this report, the WHO executive board urged member States "to exert a determined effort to maintain adequate and effective measures to reduce incidence of the endemic treponematoses, particularly those of childhood, and the venereal

diseases and, where indicated, to increase their efforts to combat, at the national level, the recrudescence of these infections".

### Psychiatry In General Practice

A PRICE has to be paid for every advance in medicine. With mental disease, for example, an increasing burden is laid on the family doctor by the policy of the 'open door'. The wisdom or charity of this new concept of retaining the mentally disturbed patient in the community is generally accepted, although the family doctor may wonder whether the enthusiastic progenitors of the concept have ever realized what it means to him. He is willing to cope with the situation to the best of his ability, and the aim of a symposium in *The Practitioner* (194, No. 1163; 1965) is to help him in his onerous task. In the available space only a few aspects of the subject are considered. Those included have been selected either because they represent conditions commonly encountered, such as depressive illness which, as Dr. J. Pollitt points out, is the commonest psychiatric condition in general practice, or deal with new developments in this field such as therapeutic communities. The symposium concludes with an article on "The Neurotic in General Practice", which epitomizes one of the most worrying problems facing the family doctor at the present moment. Dr. N. Kessel notes that "Until the theoretical understanding of how to treat neurosis is achieved, until there is considerably more money to spend within the N.H.S. [National Health Service], the problem of how to manage the mass of neurotic patients known to their doctors cannot be satisfactorily solved". This gloomy outlook is relieved by the evidence that "there is a high proportion of spontaneous remissions". In other words, "most neurotic patients get better".

### The International Hydrological Decade

In November 1961, on the authority of the U.S. Department of State, a resolution was tendered to the Executive Board of Unesco "... calling attention to the importance of scientific hydrology and recommending that a meeting of experts should be convened, to examine the proposition to institute an international programme for hydrology, extending over a ten-year period". The General Conference of Unesco, in November 1964, approved the plans prepared by meetings of these experts for an International Hydrological Decade, to start in January 1965. The events leading up to this decision have been recorded by R. L. Nace in a paper entitled "The International Hydrological Decade" (*Trans. Amer. Geophys. Union*, 45, 413; 1964); a later and succinct account of the whole project is contained in an article similarly titled by E. S. Hills (*Austral. J. Sci.*, 27, 10; April 1965). This sets forth the main objectives of the scheme, which may be summarized as follows: (a) appraisal of the state of knowledge of world hydrology and identification of the principal gaps in that knowledge; (b) standardization of instruments, observations, techniques and terminologies used for compilation and reporting of data; (c) establishment of basic networks and improvements of existing networks to provide fundamental data on hydrological systems covering small watersheds to the world as a whole; (d) research on hydrological systems in selected environments, called 'representative basins'; (e) research on specific hydrological problems the urgency and special nature of which demand action at international level; (f) theoretical and practical training in hydrology and related subjects; (g) systematic exchange of information. E. S. Hills is chairman of the Australia-Unesco Committee for the International Hydrological Decade and in his article he gives a brief account of Australian participation in this laudable and vital scheme. This is followed in the same issue of the *Journal* by an important paper entitled "Water—Essential Factor of Economic Develop-

ment", by R. L. Nace (U.S. Geological Survey), reproduced from *Impact* (14; 1964); much of the background, both theoretical and technical, of the International Hydrological Decade is disclosed in this essay. The German version of this project is described in an article "Die Internationale Hydrologische Dekade (IHD)" by U. de Haar, Bad Godesberg (*Umschau in Wissenschaft und Technik*, Frankfurt/M, 14; July 1965); this includes a novel diagram in colour depicting the incidence and passage of rainfall in its circulation on and below the surface of the Earth, what is lost, what is used, and how the inevitable water-cycle is completed.

### History under the Sea

THE Smithsonian Institution has provided a very useful compendium of the rapidly growing work of underwater exploration in a book, *History under the Sea*, by Mendel Peterson (Pp. xiii+108+56 plates, publication 4538. Washington, D.C.: Smithsonian Institution, 1965). The subject is treated from all aspects and even discusses modern methods of spotting underwater wrecks by magnetometers and induction detectors. A useful section is devoted to the preservation of materials recovered from the water, both as regards first-aid work in the field and subsequent treatment in the laboratory. A selected bibliography and illustrations of typical finds complete this eminently worth-while publication.

### Photography and the Graphic Arts

THERE are many publications catering for the interests of photographers, both amateur and professional, but one entitled *Visual* is perhaps not so widely known as it deserves to be. *Visual* is the house organ of Ilford Ltd. (Ferguson House, 15-17 Marylebone Road, London, N.W.1), and appears three times annually. Two recent copies (2, No. 3; 1964, and 3, No. 1; 1965) are notable both for contents and certainly for the excellence of the black-and-white and colour illustrations generously distributed throughout the texts, as one would naturally expect from this particular firm. Among the titles in the former issue is "Assignment Tokyo", depicting briefly, in colour, contemporary life in this modern Japanese city; an account of the activities of the Institute of Incorporated Photographers; papers on "Photographic Paper Base", "Medical Photography", and "The Production of Photolitho Printing Surfaces for Offset Printing". In the more recent issue there are articles on "The Polytechnic Contribution to the Development of Photography"; "Printing and Publishing—15 Years Hence?"; "Photographic Processing Chemicals". The journal also includes an article entitled "Profile: Douglas F. Lawson", dealing with this internationally recognized authority on photomicrography; the colour illustrations to this are quite outstanding, ranging in subject from aspirin crystals, marine-floor foraminifera, natural onyx stone, section of a cat's tongue showing the surface hairs, and the eggs of a moth, to a section of fused phloridzin, and a reproduction of a slide of *Amphioxus*, part colour, which demonstrates the value of annotated drawings to accompany photomicrographs. Incidentally, as mentioned in this article, D. F. Lawson is the author of the well-known *Technique of Photomicrography*; his work "... has been reproduced in hundreds of publications in many parts of the world, and used in educational television programmes". *Visual* is yet another example of a high-class house magazine wherein advertisement is relegated to a modest background (a brief section entitled "Ilfordia") and the major appeal to the reader made by the quality of its contents, by its inviting format, and especially by its beautiful illustrations.

### Creep and Shrinkage of Concrete

ARTICLES, papers and books dealing with the subject of creep and shrinkage of concrete, held by the library of

the Cement and Concrete Association, are the basis of a recent publication entitled *Annotated Bibliography on the Creep and Shrinkage of Concrete* (Pp. 88. London: Cement and Concrete Association, 1965. 20s.). This derives from an extensive literature search on the factors influencing creep and shrinkage and the effect of these functions on concrete as a structural material. The results of this search are presented in three parts: an annotated bibliography of 68 publications; an Appendix (1) comprising a bibliography of more than 800 references to the subject; and an author index (Appendix 2), which greatly facilitates reference to the previous items where their names are known. In the annotated section, the years covered are from 1964 to 1967 (in that order); similarly in Appendix 1, from 1964 to 1968. The scope of this *Bibliography* is, of course, international, and for architects, civil engineers, cement and concrete technologists, and research students concerned with these problems, its possession will prove not only an invaluable guide to a widely scattered literature, but also a certain time-saver when it comes to reference work.

#### Anglo-Icelandic Field Research Group

THE Anglo-Icelandic Field Research Group was formed in 1961 to aid and co-ordinate field research in Iceland by specialists, by amateurs and by expeditions. A committee of specialists in geology, botany, ornithology, glaciology and so on deals with requests for information, bibliographies, suggestions for projects, or criticism of plans made. Informal contacts are maintained with Icelandic scientists, and otherwise elusive Icelandic scientific periodicals are subscribed to, thus allowing the most up-to-date information to be given at all times. The Group publishes a *Bulletin*, of which the third issue, just published, contains news of field work planned for the 1965 and 1966 seasons, brief notes on the progress of work undertaken in 1964, and a comprehensive review of recent scientific literature concerning Icelandic field research topics. Further items in the current issue include a comprehensive general bibliography, notes on information sources and a suggested itinerary for geologists visiting the important volcanic district of Myvatn in north-east Iceland. Further information can be obtained from the secretary of the Group, Mr. P. W. Sowan, 161 Piccadilly, London, W.1.

#### University News:

##### Bristol

DR. L. E. HAWKES has been appointed to the chair of mycology. Dr. I. M. Ward has been appointed senior lecturer in the physics of materials in the Department of Physics. The following lecturers have also been appointed: Dr. W. H. H. Banks (mathematics); Dr. B. M. H. Bush (comparative physiology in the Department of Zoology); P. W. Fitt (mechanical engineering); Dr. H. A. Osmaston (geography).

##### Southampton

DR. M. H. QUENOUILLER has been appointed to the chair of statistics in the Department of Mathematics. Dr. L. E. Tavener has been appointed reader in geography. The following lecturers have also been appointed: P. W. Fortescue (aeronautics and astronautics); P. C. Ryall (civil engineering); C. B. Chapman (econometrics); Dr. A. G. Bailey and Dr. J. A. Coekin (electronics); J. H. Dunmore (mechanical engineering); Dr. P. J. Williams (oceanography); Dr. N. Maclean and Dr. A. E. Wild (zoology).

##### Swansea

DR. J. H. PURNELL has been appointed professor of physical chemistry. Dr. T. O. Jeffries has been appointed to the newly established chair of industrial engineering. The following appointments have also been made: *Senior Lectureships*, Dr. E. G. Brown and G. T. Goodman

(botany); Dr. J. D. Davies and H. W. Goaling (engineering); Dr. H. E. Hallam (chemistry); Dr. C. N. Linden (pure mathematics); T. S. Walters (applied mathematics); *Lectureships*, T. H. Walton (pure mathematics); Dr. J. T. Davies and Dr. R. Phythian (physics); Dr. J. H. Williams (chemistry); Dr. D. T. Herbert (geography); Dr. J. S. Ryland (marine biology in the Department of Zoology); Dr. R. A. E. Tilney-Bassett (genetics in the Department of Zoology).

#### Announcements

Dr. J. W. Cornforth and Dr. G. J. Popjak, of the Milstead Laboratory of Chemical Enzymology, Shell Research Ltd., have been jointly awarded the first OIBA Medal of the Biochemical Society for their fundamental work on the biosynthesis of cholesterol and the stereospecificity of enzymatic reactions. The Medal will be awarded annually in recognition of outstanding research.

THE next awards of the Ethel Behrens Fund of the Chemical Society are to be made in connexion with their anniversary meetings to be held in Oxford in March 1966. This fund provides grants towards travelling and maintenance expenses to help Fellows of the Society studying for a degree at a British university or technical college to attend the anniversary meetings of the society. Application forms and further information can be obtained from the General Secretary, the Chemical Society, Burlington House, London, W.1.

THE autumn meeting of the Chemical Society will be held in the University of Nottingham during September 21-22. Further information can be obtained from the General Secretary, the Chemical Society, Burlington House, London, W.1.

A SYMPOSIUM on "Reservoir Yield", organized by the Water Research Association, will be held at the University of Oxford during September 21-23. Further information can be obtained from the Water Research Association, Medmenham, Marlow, Bucks.

A CONFERENCE on "The Fundamentals, Production and Applications of Hard Magnetic Materials" will be held in Vienna during September 21-24. Further information can be obtained from Verein Deutscher Eisenhüttenleute, 4 Düsseldorf, Breite Strasse 27.

A SYMPOSIUM on "Food Science Research in the United Kingdom" will be held at the School of Pharmacy, University of London, on September 22. Further information can be obtained from the Assistant Secretary, Society of Chemical Industry, 14 Belgrave Square, London, S.W.1.

A SYMPOSIUM on "Modern Trends in Space Physics", organized by the British Interplanetary Society, will be held at University College, London, on September 23. Further information can be obtained from the Executive Secretary, the British Interplanetary Society, 12 Beesborough Gardens, London, S.W.1.

A TWO-WEEK summer school on "Methods of Numerical Approximation", organized by the University of Oxford Computing Laboratory and the Delegacy for Extra-mural Studies, will be held in Oxford during September 20-October 1. Further information can be obtained from the Secretary, Delegacy for Extra-mural Studies, Rewley House, Wellington Square, Oxford.

THE fifth international Aerosol Congress and the third International Aerosol Exhibition, organized by the Italian Aerosol Association on behalf of the Federation of European Aerosol Associations, will be held in Milan during September 21-26. Further information can be obtained from the British Aerosol Manufacturers' Association, Cecil Chambers, 86 Strand, London, W.C.2.

## FEDERATION OF EUROPEAN BIOCHEMICAL SOCIETIES

By DR. J. R. VILLANUEVA

Instituto de Biología Celular, C.S.I.C., Madrid

THE Federation of European Biochemical Societies was founded in 1964 to promote contacts and the interchange of information between European biochemists. It now comprises twenty-one Societies. Much of the work of the Federation is concentrated on a comparatively few clear-out projects including organization of meetings and courses in advanced research techniques. Meetings are held every year at some centre of research where symposia are held and a number of papers dealing with the most recent research topics are delivered. Two meetings have been organized; the first in London in 1964 and the second in Vienna in 1965. The third Federation meeting will be held in Warsaw in April 1966.

Organized by the Société Belge de Biochimie, the first summer course of the Federation of European Biochemical Societies was held at the Catholic University of Louvain during June 8-18; the subject was "Centrifugal Fractionation of Animal Cells: Theoretical Basis and Practical Procedures". The course, which was organized in detail by the Department of Physiological Chemistry, Institute of Physiology, gave a very wide view of the problem through lectures and practical demonstrations. It was sponsored by the Federation of European Biochemical Societies and the International Cell Research Organization of Unesco, which provided grants covering half the expenses of all the participants, who numbered about 20 and represented more than 15 nationalities; the places had been selected from a large number of applications. English was the official language of the course.

To comment on the importance of selecting the topic of separation of macromolecules and particles, it should be remembered that it is significant that some of the most remarkable recent advances in biochemistry have depended on new and improved separation procedures. Findings on the behaviour of a component in a separation process dependent, for example, on sedimentation velocity, provide a convenient basis for preliminary quantitative characterization. If such work is done systematically in correlation with investigations of biochemical function and with electron microscopy studies it may provide very interesting information which would have been difficult to obtain by other means.

Prof. C. de Duve (Department of Physiological Chemistry, University of Louvain, and Rockefeller Institute, New York) was the chairman of the course. Specialists will not need to be told that the science of centrifugation has made considerable progress during the past decade and that the Louvain group has made important contributions in this field.

Prof. de Duve described the general principles of centrifugal fractionation, theory of sedimentation, analysis of sub-cellular fractions, differential centrifugation in homogeneous medium, density gradient, isopycnic centrifugation, and the calculation, presentation and interpretation of results. Prof. J. Berthet (Department of Physiological Chemistry, Louvain), who was responsible for the internal and scientific organization of the course, together with Drs. H. Beaufay and P. Jacques, gave lectures on homogenization, centrifugation equipment, density gradient centrifugation, practical procedures, density gradient differential centrifugation and density gradient centrifugation for analysis of macromolecules. Prof. Drochmans (Department of Experimental Cytology, Institut Bordet, University of Brussels) gave a lecture and practical demonstration of the preparation of particulate glycogen; Dr. D. B. Roodyn (Department of Biochemistry, University College, London) described methods of preparing nuclei, and Prof. E. Schram (Department of Animal

Morphology, University of Brussels) gave a lecture on density gradient differential centrifugation and analysis of ribosomes and polysomes, followed by a very fascinating demonstration.

Practical experiments and demonstrations were also supervised by Profs. Berthet and H. Beaufay, Drs. P. Jacques, A. Trouet, G. Vacs, M. Robb and Thines-Sempoux (Department of Physiological Chemistry of Louvain), Drs. A. Burny, G. Huez and G. Marbaix (Department of Biological Chemistry, University of Brussels) and Prof. R. Wattiaux (Department of Physiological Chemistry, Namur), and took place in the laboratories of the Department of Physiological Chemistry of the Institute of Physiology. Fundamentally, the practical work comprised the preparation of gradients and a general but very detailed survey of the techniques of centrifugal fractionation, in which cells were disrupted in a homogenizer and then spun in a centrifuge at successively higher speeds to yield a number of fractions containing organelles of different types. The organelles were then explored by means of biochemical methods determining the association of a number of enzymes with the cellular structures. The importance of this systematized technique has been dramatically emphasized in recent years by the isolation of a new cell organelle, the lysosome, which has already been shown to have fundamental importance for cell biology.

The organization of the course was well carried out. Equipment was of a high order and very specialized, and a team of expert assistants helped so that participants were able to obtain the maximum advantage. This report would be incomplete without recording the appreciation of the participants for the excellent arrangements made by Prof. H. G. Hers, who assumed the administrative responsibility of the course with meticulous attention to detail, and for the hospitality extended to them.

Mention must be made of the enthusiasm of Prof. C. Liébecq, secretary of the Société Belge de Biochimie in persuading Prof. de Duve to start a new line for the Federation of European Biochemical Societies with this course and in particular for the Society's ready willingness at all times to co-operate with the scientific staff and participants in providing the required facilities.

To sum up the course, Prof. C. de Duve's group attempted in the lectures and practical work to draw an overall and consistent picture of the succession of processes constituting a mechanism of separation of sub-cellular particles. The participants of the course were given every facility to appreciate the methods developed by these skilled specialists, and the progress which can result from detailed analysis of the enzymatic properties of sub-cellular particles separated by differential and density gradient centrifugation and from the characterization of the various particles. The course, which was much appreciated by those present, ended with a general discussion of the practical results.

This first summer school of the Federation brought together biochemists of many different specialities. Throughout the course an atmosphere of the greatest cordiality and friendship prevailed. Many problems of common interest were discussed, and evening meals at the Faculty Club of the University, a beautiful and modern building, kept members gathered together after the laboratory work. The course in fact performed two interesting functions: one European and the other scientific. An official dinner was held on June 11, and presided over by Prof. C. de Duve. A succession of national toasts was offered by the participants to the staff of the Depart-

ment and the organizers, one representative of each country thanking in his own language the staff and all the people collaborating in the success of the course. In reply, Prof. de Duve thanked all the participants for their co-operation and expressed his satisfaction with the result of this first summer school; he expressed the conviction that this would be the starting point for a series of similar courses for which interest was amply evident.

The Federation of European Biochemical Societies is to be congratulated on organizing courses of such quality.

The general nature of this kind of course will ensure its future success, and there is clearly no shortage of subjects. The importance of ensuring conditions that will facilitate free international co-operation and interchange in any field of scientific endeavour is not small, and the organization of this course is an important new landmark in the development of relations among scientists of different countries. We are sure that in the very near future similar meetings will be held in other biochemical institutes.

## BIOCHEMISTRY IN MAGDEBURG

WE have recently returned from a short visit to East Germany, where we were invited, as guests of the G.D.R. Government, to participate in the second annual conference of the Biochemical Section of the Society for Experimental Medicine of the G.D.R. held at Magdeburg during June 24-26.

The conference was held at the Medical Academy in Magdeburg under the presidency of Prof. K. Lohmann. It was attended by about 300 biochemists, including a notable group from the Federal Republic of Germany and representatives of many countries of Eastern and Western Europe. Prof. Eberhard Hofmann, of Magdeburg, in his organization of the conference, followed the best traditions of international scientific meetings.

The meeting centred about three symposia: (a) "Functional Biochemistry of Cell Membranes and Mitochondria"; (b) "Problems of the Regulation of Glycolysis and Fermentation"; (c) "Aspects of the Training of Biochemists". There were also sessions where short communications were read. In all, about 100 papers were heard.

By far the most interesting event was the symposium on glycolysis and fermentation. This session, conducted admirably by Prof. H. Frunder, of Jena, was introduced by Prof. Benno Hess, Dortmund. In his exposition, Hess centred his arguments on mathematical models of glycolysis and on the oscillatory behaviour of metabolites under transitional conditions in living yeast and in yeast press juice. The importance of phosphofructokinase in regulatory mechanisms was emphasized in many contributions. Thus Hommes (Nijmegen) described a number of phosphofructokinases in different yeasts which were all inhibited by ATP. The phosphofructokinases from yeasts that showed an aperiodic change in pyridine nucleotide levels after anaerobiosis were activated by fructose-6-phosphate and not by AMP, while the enzymes from 'asymptotic' yeasts were activated by neither of these compounds. 'Oscillatory' yeasts had phosphofructokinases which were inhibited by ATP and activated by fructose-6-phosphate and AMP. Freyer and Kopperschlager (Magdeburg)

suggested that the high aerobic glycolysis of ascites tumour cells could be explained by the insensitivity to ATP of the phosphofructokinase, together with the low pyruvate utilization and the limited power of the mitochondria to oxidize cytoplasmic NADH. The inhibition of glycolysis in ascites tumour cells by alkylating cytostatic agents appears to be due to an activation of NAD-splitting enzymes (Grunicke, Richter and Holzer, Freiburg). Lamprecht (Munich) discussed the regulation of glycolysis in human heart muscle. Rapoport (Berlin) considered the regulatory significance in erythrocytes of an NADP-dependent lactate dehydrogenase and, in ascites tumour cells, of a lactate oxidase not requiring a pyridine nucleotide.

In the symposium on the training of biochemists, we learned from Prof. Hofmann's introductory remarks that courses for biochemists in the Faculty of Science existed in only two German universities: Tübingen in the West and the Humboldt University in East Berlin. Hofmann emphasized the need for additional courses of this kind. We had the opportunity of describing the existing courses in London and some of the proposed developments in Britain's new universities. Prof. Bücher (Munich) expressed enthusiasm for the relative brevity of degree courses in Britain and was joined by Prof. Rapoport (Humboldt University, Berlin) in a plea for the elimination of the time-consuming medical course as a prerequisite for a biochemical career in Germany. It was evident that these matters were of vital interest to the younger members of the conference.

We were impressed by the high quality of the scientific work as it was described in the communications and by the evident desire of our East German colleagues to improve their contacts with the countries of the West. It is deeply disturbing that the absurdities of politics make it difficult for us to contribute to this improvement and to make a full return for the hospitality which we received.

D. F. CHERRMAN  
J. R. LAGNADO

## INDUSTRIAL FEEDING AND CANTEN MANAGEMENT

THE report on the joint symposium on "Industrial Feeding and Canteen Management in Europe", held in Rome during September 2-7, 1963, has now been published under the auspices of the Food and Agriculture Organization, the International Labour Organization, and the World Health Organization\*. After explaining the reasons for the interest of these organizations in the subject, the report summarizes the situation to-day in various European countries and suggests some steps to

be taken if these specialized agencies are to assist member countries to solve their more urgent problems.

In most European countries industrial feeding is regarded as an integral part of the facilities of the factory, even though the provision of food to workers is frequently not required by law. The determining factor in provision of a canteen and in the type of service offered is usually the demand and need of the workers. The use of canteen services varies in different countries and is often disappointingly small. The effect of nutrition on occupational health and on working efficiency and such matters as food supply, levels of food consumption and food habits, as well as the problems encountered in pro-

\* Food and Agriculture Organization of the United Nations. FAO Nutrition Meetings Report Series, No. 36: *Report of the Joint Symposium on Industrial Feeding and Canteen Management in Europe, Rome, Italy, 2-7 September, 1963*. Pp. 44. (Rome: Food and Agriculture Organization of the United Nations. London: H.M.S.O., 1964.) 2s. 6d.; 50 cents.

moting acceptance of improved diets, are dealt with in successive chapters.

The symposium agreed that the newer knowledge derived from research in the behavioural sciences must be taken into account when planning for the educational aspects of canteen operation. It was suggested that much more attention should be directed to scientific research on food habits and food preferences among specific groups of workers in particular areas, on rates and channels of change in nutritional and diet practices, the effectiveness of different types of activities, and the results of educational methods and materials used. It was considered that carefully planned training in educational methods of techniques, as well as in relation to the psycho-social and cultural determinants of human behaviour about nutrition, should be included in all professional courses for people who would be responsible at a relatively high level for the management of industrial canteens.

Participants at the symposium urged the need for more exchange of information and better distribution of current literature. A suggestion was strongly supported that an international organization, possibly the Food and Agriculture Organization, should establish a clearing house for current literature, research and information on the nutrition of workers. It was also recommended that a

joint study group of specialists in industrial feeding and canteen management should be sponsored by the three Specialized Agencies. Such a study group, meeting at regular intervals, could co-ordinate and, where necessary, sponsor investigations and research in industrial feeding and suggest suitable planning and methods of research into the various aspects of industrial feeding. These might include food consumption and nutritional status of workers; times and amounts of food required by workers in relation to the type of work and the work environment; the influence of time-intervals between meals, length of meal periods and amount of food consumed on workers' efficiency; the psycho-social, socio-economic and cultural patterns that lead to the use or disuse of industrial feeding units; new foods and food processing methods; kitchen planning and lay-out in relation to work efficiency, quality of food and economic production; kitchen equipment, its use and upkeep; training and education of managers, supervisors and workers; education in nutrition for industrial workers. It was also suggested that the group could study with specialists, the Governments concerned, and organizations of employers and workers any additional problems related to industrial feeding and encourage the development of a uniform system of terminology to facilitate exchange of information in this field.

## NATIONAL COAL BOARD MINING RESEARCH ESTABLISHMENT

THE Mining Research Establishment held open days during July 19-23, of which three days were reserved for overseas delegates to the fourth International Mining Congress and two days for visitors from Great Britain. The demonstrations illustrated the wide application of the research results to mining problems.

Much effort has been put into supporting the National Coal Board's drive to offset by instrumentation the reductions in manpower expected in the future. On the coal face, automatic steering of the getting machine to keep it in the coal poses problems analogous to those met in the guided-missile field. Information as to the position of the machine is supplied by a nucleonic device that measures the thickness of coal left above or below the machine in terms of the back-scatter of gamma rays directed into the floor or roof from a radioactive source. The vertical orientation of the machine is given by a tilt transducer, and the two signals are fed into an electronic control unit operating the steering jacks. The actual system required depends on the delays inherent in the input and output sides and on the geometry of the machine, characteristics which vary with each type of machine. A certain amount of information has to be obtained from full-scale field observation, but the amount of field work is kept within practical bounds by simulating transducer outputs and machine performance on an analogue computer.

Remote-control techniques have already been successfully applied experimentally on the coal face to control both getting machine and roof supports, and the Mining Research Establishment is heavily involved in the extension at Bevercotes Colliery of analogous techniques to give remote control of other sectors of the mine and to communicate production information to central points underground and on the surface as an aid to management.

Almost all underground instrumentation, whether for remote control, monitoring or research, must be intrinsically safe, that is, incapable under any conditions of operation or failure of producing a spark of energy sufficient to ignite a methane-air mixture. Research at the Mining Research Establishment on inductive break-sparks has shown that ignition can be brought about at an energy-level one-fifth of that hitherto accepted as the minimum and of the same order as that previously asso-

ciated only with capacitative circuits. This lends support to the minimum energy concept of ignition which can be applied to the design of intrinsically safe circuits. Two new protective devices, the Zener diode and the surge arrester, have been introduced into this field.

Experiments on the mode of breakage of rock and coal under simple forces or when attacked by tools have led to a theory of breakage based on brittle fracture. The deductions have led to a rationalization of the design of mining tools and machinery to give faster production for less power with the added benefits of a larger product and less dispersion of respirable dust and firedamp. Systematic study of the forces and movements around mine workings is suggesting improvements in the design and use of supports. Comparison of results obtained with those reported elsewhere indicates that many of the basic phenomena follow the same laws in all coal-fields of the world.

A considerable amount of research is directed to increasing the safety of the atmosphere in the mine by reducing the dangers from firedamp accumulations and from the respirable (1-5  $\mu$ ) dust which causes pneumoconiosis. Airflow near the coal face is studied using scale models in which the flow patterns are made visible by illuminating tracer particles suspended in water. Results have been verified underground by ventilation surveys and by the use of tracer gases and smoke. Tracer gas is also one of the means used for studying the dispersion of firedamp from the coal seam. The Mining Research Establishment has pioneered the development of instruments for sampling respirable dust. The 'long-running thermal precipitator' samples the respirable fraction of the dust in the air during a full shift. The sample is usually evaluated by counting, but an optical densitometer has been designed which gives a rapid evaluation either in number of particles or mass. A gravimetric dust sampler collects a sample, again during a whole shift, on a fibreglass filter. Accuracy of evaluation is considerably higher than that with the 'long-running thermal precipitator' and mass is probably a more important parameter clinically than particle count. Research on dust dispersion and suppression has shown the overriding importance of good design, maintenance and use of machinery so as to minimize dust formation and

dispersion. The most effective ways of using water for dust suppression have been demonstrated and the use of exhaust ventilation with filtration is being studied.

Each year the National Coal Board spends something like £100 million on metal products: working out proper specifications of the materials involved is an important part of the work at the Mining Research Establishment. Of equal importance are investigations to ensure that advances in metallurgical science are applied to modern mining techniques. Corrosion can cause serious losses and mine waters vary widely in pH and salinity. Research into the resistance of different steels to the various contaminations and the protection afforded by metallic and other coatings is aimed at minimizing corrosion losses. Oil-in-water and invert emulsions are being introduced underground as fire-resistant substitutes for hydraulic oils. The stability and corrosion-inhibiting properties of these fluids are therefore being studied in addition to the relationship between their physical properties and performance. Aqueous glycols and phosphate esters are also being examined in this context.

A requirement peculiar to steels for mine supports is that they shall withstand repeated slow plastic bending; safety demands that neither initially nor after such treatment shall they be liable to brittle fracture. The value in these conditions of heat-treated carbon manganese steels has been established and means are being sought of further increasing strength without embrittlement in a continual effort to reduce the size and weight of mining equipment. The advantages and possible dangers of the use of high-strength steels, including spring steels, are being studied with the same objective. The fatigue properties of alloy

steels for suspension gear have been determined with and without stress raisers. From this work the degree of advantage of alloy steels over manganese steel as used at present has been determined.

Cemented carbides and other hard facings are being studied to establish the best compromises for different mining tools between abrasion- and chipping-resistance. An electron microscope is being used to further this work. Methods of brazing the carbide tips on to the tools are included in the study.

Nearly 8 million yards of conveyor belting is used in British collieries and specification tests have been evolved for fire-resistant belting. The tests include not only fire resistance and performance but also surface electrical resistance in order to ensure that static charges do not build up on the surface of the plastic (polyvinyl-chloride), which has replaced flammable rubber in underground belting. The same problems of fire-resistant and anti-static properties arise with all plastics used underground and there is a steady stream of articles arriving at the Mining Research Establishment for examination as underground applications are found for these new materials.

Conveyor belting has improved enormously in strength over recent years; it has been necessary to improve methods of jointing. A new type of fastener has been devised at the Mining Research Establishment which gives a performance several times better than fasteners at present in use, and work is continuing further to improve jointing methods. Simultaneously the fastener-holding properties of belts are being examined and the effect of varying the fabric in the carcass is being determined.

C. S. MAKOWER

## DEFORMATION OF SOLIDS BY THE IMPACT OF LIQUIDS, AND ITS RELATION TO RAIN DAMAGE IN AIRCRAFT AND MISSILES, TO BLADE EROSION IN STEAM TURBINES, AND TO CAVITATION EROSION

By DR. J. H. BRUNTON, DR. J. E. FIELD and G. P. THOMAS

Physics and Chemistry of Solids, Cavendish Laboratory, Cambridge

A DISCUSSION on "The Deformation of Solids by the Impact of Liquids" was held by the Royal Society on May 27. In his opening remarks, Dr. F. P. Bowden, who had organized the discussion, stated that the meeting would begin by considering the physics of liquid impact and the nature, magnitude and duration of the stresses which are produced when a solid is struck by a drop of liquid. Even with moderate impact velocities the pressures developed in the solid are considerable, and at high velocities the shock pressures are very great indeed and are sufficient to produce deformation of the strongest solids. These observations have a bearing on three technical problems which are of considerable importance at the present time. The first is the damage caused to a high-speed aircraft or missile when it strikes a raindrop. The second is the erosion of turbine blades rotating at high speed in wet steam. The third is the damage produced by 'cavitation' in liquids. There is now evidence that the stress due to liquid impact is a common factor in all three of these processes. One interesting development of this work is that liquid impact is being used as a practical method for 'cutting' or fracturing solids.

In the section on the physics of impact, papers by Dr. J. H. Brunton and Dr. J. E. Field (Cavendish Laboratory, Cambridge) described investigations of the high-speed impact of cylindrical and spherical drops on hard surfaces. At velocities in the region of 1,000 m/sec, they found that the impact pressures reached values of about 370 kg/mm<sup>2</sup>, a figure appreciably greater than the strength of many

common structural materials. They found that the behaviour of the drop on impact was adequately described by the 'water-hammer' equation. The main characteristics of this behaviour were an initial short duration (1-2 μsec) water-hammer pressure and a high-speed flow from under the impacting drop. The large magnitude and short duration pressure peak gave the drop impact an 'explosive' character and the high-flow velocities led to erosion at surface discontinuities in the target specimen. In brittle materials the impact characteristics gave rise to ring fracture patterns, and in metals to smooth depressions with eroded edges. In thin-plate specimens 'scabbing' (spalling) occurred near surfaces where the compression wave was reflected. The influence of surface flaws on failure in brittle materials was described.

An interesting account of the high-speed jets which arise when concave liquid surfaces collapse under pressure from behind was given by Dr. F. P. Bowden (Cavendish Laboratory, Cambridge). Examples were shown of liquid Munroe jets, and of jets formed in collapsing cavities and between coalescing drops. The implications of jet formation in cavitation were discussed in a later paper by Dr. T. Brooke Benjamin and Prof. A. T. Ellis.

Sir Geoffrey Taylor (Cavendish Laboratory, Cambridge) described an investigation of the problem of the oblique impact of a liquid jet on a plane surface. The transformation of the jet into a thin sheet was examined and compared with experiment. The maximum steady-state pressure was always the stagnation pressure, but it

seemed that much higher pressures were possible if the jet was moved sideways during impact.

A useful method for investigating the impact force produced by a liquid drop using a dislocation etch-pit technique was described by Dr. K. H. Jolliffe (Central Electricity Research Laboratories, Leatherhead). The method depended on comparing the size of the etch-pit 'rosettes' produced by a steel ball, for which the stresses can be calculated, with the size of the rosettes produced by the impact of a liquid drop.

Multiple impact experiments were described in papers by Mr. G. P. Thomas (Cavendish Laboratory, Cambridge), and by Dr. J. B. Marriott and Dr. G. Rowden (English Electric Co., Ltd., Whetstone). In Mr. Thomas's experiments the initial stages of deformation were examined for very low impact velocities, and at stresses well below the yield strength of the metals used. It was observed that the metal deformed initially only in small 'weak' areas (approximately 1  $\mu$  in diameter) forming depressions. Some depressions grew and eventually metal was eroded either by ductile or brittle failure in these larger depressions. In the paper by Drs. Marriott and Rowden the specimens were cobalt-based stellites eroded at high-impact velocities. They found general deformation by slip in the softer matrix at an early stage and observed flaring and pitting at phase boundaries. Erosion occurred as a result of cracking at the carbide/matrix boundaries.

When the discussion turned to the rain erosion of aircraft the problem was reviewed by Mr. A. A. Fyall (Royal Aircraft Establishment, Farnborough). Factors including component design, velocity of flight and rain intensity were discussed, together with their significance in practice. One point which emerged was the possibility of rain at quite high altitudes (> 30,000 ft.). However, commenting on this, Mr. R. F. Jones (Meteorological Office) said that the probability, although not negligible, was very small. Droplets would only form in association with vigorous convection currents and over limited horizontal distances; when they did occur they should be detectable by radar.

The possibility of rain droplets being disintegrated by the shock waves travelling ahead of fast-moving bodies was considered in a paper by Mr. D. C. Jenkins (Royal Aircraft Establishment, Farnborough). It was shown that although the droplets do start to break up in the shock the process takes a finite time. A combination of experiment and theory has enabled Mr. Jenkins to evolve an equation relating the time of break-up to the drop diameter and the velocity of the airstream.

Work in progress in Germany was reported by Dr. H. Busch (Dornier-System G.m.b.H., Friedrichshafen, Germany). A considerable achievement in their experimental programme has been the successful design of a rotating arm apparatus capable of reaching velocities of Mach 1.5. By operating the device in an atmosphere of simulated rain, a wide range of materials had been tested for their erosion resistance. High-speed photographs showed that during impact the water droplets disintegrated into a fine spray which quickly evaporated; this 'mechanical vaporization', under some conditions, caused cooling of the solid surface, a result of some relevance in the problem of the icing-up of aircraft.

In the next part of the meeting Mr. J. Caldwell (English Electric Co., Ltd., Rugby) described the damage found on steam turbine blading, and discussed the effect it had on the design and efficiency of turbines. Attempts at removing the water, shielding parts of the blade with more resistant material and increasing the spacing between rotating and stationary blades had achieved partial success.

Dr. T. Broom (Central Electricity Research Laboratories, Leatherhead) presented a paper by Dr. D. G. Christie and Mr. G. W. Haywood (Central Electricity Generating Board) on the formation of the water droplets which cause erosion in steam turbine. A film of the conditions inside a turbine was presented which showed how

water collected in large quantities on the stationary blades and was then afterwards swept off by the steam into the path of the rotating blades. Steam tunnel experiments were also described, and films showed the size, velocities and behaviour of drops in the steam flow.

In a paper by Mr. D. W. O. Baker (Central Electricity Generating Board, South-east Region), Dr. K. H. Jolliffe and Mr. D. Pearson (Central Electricity Generating Board, Marchwood), the form and microstructural characteristics of erosion damage in turbine blade materials were described. The progress of the damage was illustrated and a relation for the erosion resistance of a material was given. This relation was interpreted in terms of a fatigue mechanism of damage.

The session on cavitation was opened by Dr. T. Brooke Benjamin (Department of Applied Mathematics, Cambridge), who presented a paper by himself and Prof. A. T. Ellis (California Institute of Technology, Pasadena), and also one by Prof. M. S. Plesset (California Institute of Technology, Pasadena), who could not attend. The papers were concerned with the collapse of cavitation bubbles and the pressures produced. A particularly interesting point which emerged was that there is now considerable theoretical and experimental evidence to show that a cavity collapsing near a solid boundary may develop a jet of liquid by involution of its far side. This high-speed jet then passes through the cavity and may strike the solid boundary. Although the contribution of this phenomenon to cavitation damage has yet to be established, it seems likely that it will prove important.

Prof. F. G. Hammit (University of Michigan, Ann Arbor) was primarily concerned with the damage in materials caused by cavitating flow. The observed pitting was a mixture of randomly located symmetrical pits, presumably the result of single events, and irregular fatigue-type failures. There were interesting similarities between some of the pits illustrated by Prof. Hammit and those shown earlier for droplet erosion damage. The closeness with which cavitation and liquid impact erosion are linked was emphasized in the contribution of Dr. J. M. Hobbs (National Engineering Laboratory, East Kilbride) on the practical aspects of cavitation; one of the accelerated tests used by Dr. Hobbs for evaluation of cavitation erosion resistance was, in fact, a drop impact apparatus. Dr. Hobbs found that in this test the velocity of collision and the jet diameter had significant effects. These observations agree well with the present picture of the physics of the impact process, since the magnitude of the 'water-hammer' pressure depends on the velocity of impact, and its duration on the jet diameter.

The final paper, by Dr. S. J. Leach and Dr. G. L. Walker (Safety in Mines Research Establishment, Sheffield), considered the application of high-speed liquid jets to cutting. Fine jets had been produced at velocities up to 1,000 m/sec; the maximum velocity being produced by pressures of 5,000 atm. A detailed study of nozzle design, and of the pressures produced by the impacting liquid, had been made. Optical and X-ray photography demonstrated that the jet was by no means completely atomized at the nozzle, but had a central coherent core. Although the full potentialities of this method have yet to be evaluated, it is hoped that this form of cutting will prove useful in mining where frictional heating from more conventional cutting appliances can cause ignition of methane gas.

Prof. K. K. Shalnev (Institute of Mechanics, Moscow), who had prepared a paper on scale effects in cavitation, was unable to be present, but his contribution, together with the other papers and discussion, will be published in the *Proceedings of the Royal Society* dealing with the meeting. The meeting was attended by some 150 physicists and engineers from different countries.

In his closing remarks the president, Lord Florey, emphasized the importance which the Society attached to this interplay between science and technology.

# GEOMAGNETIC DEPTH-SOUNDING AND CORRELATION WITH OTHER GEOPHYSICAL DATA IN WESTERN NORTH AMERICA

By B. CANER

Victoria Magnetic Observatory, Dominion Astrophysical Observatory, Victoria, Canada

AND

W. H. CANNON

Department of Geophysics, University of British Columbia, Vancouver, British Columbia, Canada

THE geomagnetic depth-sounding method is based on the comparison of variations in the natural geomagnetic field recorded at different locations. The vertical component in particular reflects the distribution of electrical conductivity at the depths where the bulk of the induced currents flow. For fluctuations of intermediate period (500–1,000 sec) the penetration depth is sufficiently large to permit use of the method for upper mantle research. The method is as yet insufficiently developed to permit direct quantitative interpretation; but it can provide a very powerful tool if used in conjunction with other geophysical information. A possible correlation between the geomagnetic 'coast effect' and discontinuities in the seismic low  $S$ -velocity layer has been suggested<sup>1,2</sup>. The apparent coincidence between seismic low  $P$ -velocity zones and some inland anomalies<sup>3,4</sup> has also been pointed out<sup>5</sup>.

The present communication presents the application of such a combined geophysical approach to the particular case of western North America. The available geomagnetic data<sup>6-7</sup> are summarized in Fig. 1. The ratio  $I = |\Delta Z|/[(\Delta D)^2 + (\Delta H)^2]^{1/2}$  (ratio of vertical to horizontal component amplitudes) is derived from peak-to-peak amplitudes of fluctuations in the range of periods 10–120 min. It is a somewhat crude parameter, and cannot be readily interpreted in the immediate vicinity of lateral discontinuities. However, it is very useful for comparisons between 'normal' stations (that is, over horizontally stratified distributions in conductivity) at roughly similar geomagnetic latitudes. Consistently lower  $I$ -ratios at any group of stations indicate that the external vertical component is being compensated more effectively by induced internal contributions, that is, that the highly conducting layers lie nearer to the surface than at other stations with higher  $I$ -ratios. In this particular case the contrasts in  $I$ -ratios are sufficiently large (changes by factors of 2–3 over distances of 100–200 km) to permit valid comparison of the results without more sophisticated analysis. At anomalous stations (shown circled) the recorded fluctuations differ significantly from those recorded at stations on either side; they can be assumed to be within 50–100 km of major lateral discontinuities. As Schmucker<sup>8</sup> pointed out, only these stations can be considered truly 'anomalous'; all others (whatever their  $I$ -ratios) are 'normal' for the particular horizontally stratified conductivity structure of the region. The anomalous stations shown near the coast represent the geomagnetic 'coast effect'<sup>9,10</sup> and are not directly relevant to the present investigation.

Some of the available seismic results<sup>11-14</sup> have also been summarized on Fig. 1. Those in the south-western United States are sufficiently dense to permit  $P_n$  velocity contours to be drawn<sup>5</sup>; the results in the north-west are as yet too sparse for reliable contouring, but tentative results indicate that the structure turns sharply to the north-west from about lat. 48° N. (ref. 15). In both cases the edge of the seismic low  $P_n$  velocity zone is roughly correlated with the edge of the geomagnetic low- $I$  zone, in location as well as strike. Exact spatial correlation cannot be expected, since seismic  $P_n$  data represent

average values over fairly long distances; also the relevant 'edge' would be a transition band between about 7.0 and 8.1 km/sec, rather than the 8 km/sec contour.

The foregoing comparison demonstrates the possible value of geomagnetic depth-sounding as a complementary method to seismic refraction work. Large areas can be economically surveyed by geomagnetic depth-sounding to find the location (and possibly the strike) of lateral discontinuities. These can then be investigated quantitatively by parallel seismic profiles on either side. Apart

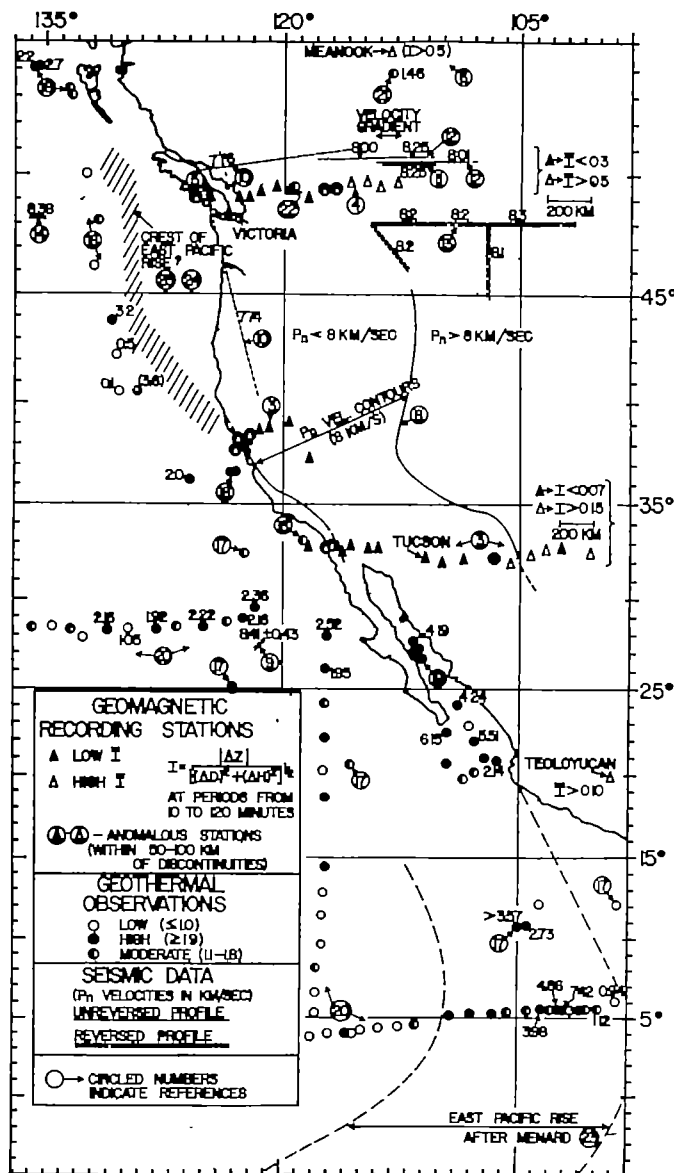

Fig. 1. Geomagnetic and other geophysical data, western North America.

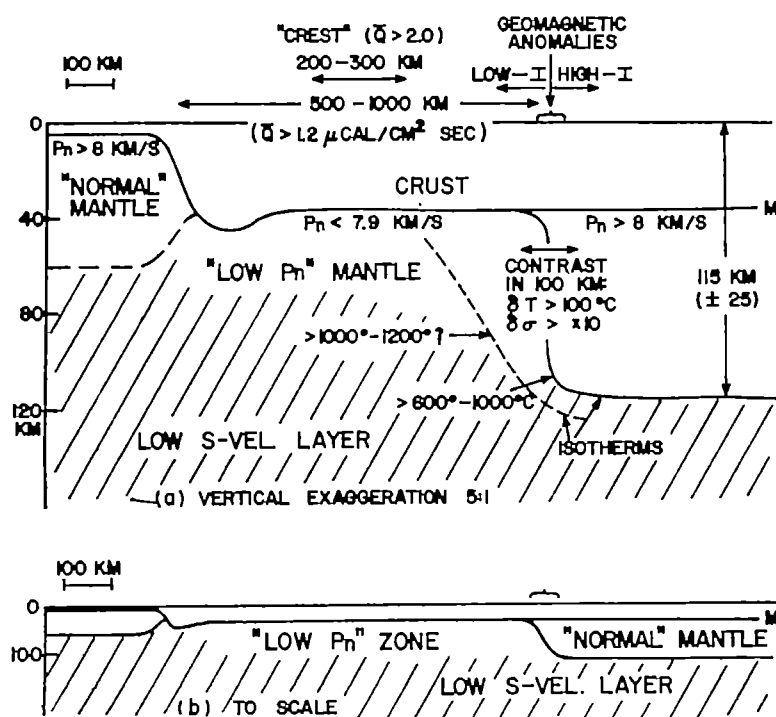

Fig. 2. Generalized upper mantle model, western North America

from this practical aspect of geographical delineation, the correlation between seismic low-velocity and geomagnetic low- $I$  zones carries implications about the nature of these zones. Since the electrical conductivity at upper mantle depths is primarily a function of temperature, the correlation lends strong support to the hypothesis that the low  $P$  velocities are caused primarily by increased temperatures rather than by changes in composition. The low  $P_n$  velocity zone in California has generally been interpreted on the basis of composition changes. In at least one case, however<sup>16</sup>, it was suggested that increased temperatures (by about 200° C at depth 30 km) could improve the consistency between gravity data and seismic  $P$  delays. This suggestion is strongly supported by the existence of major geomagnetic anomalies associated with the low  $P$ -velocity zones.

Indirect support for this hypothesis of increased upper mantle temperatures under western North America comes from the pattern of heat flow observations<sup>17-23</sup> shown in Fig. 1, and from the suggested continuation of the East Pacific Oceanic rise under the continent<sup>24</sup>. The East Pacific rise is characterized by a broad belt (about 200-1,000 km wide) of moderately high (more than 1.2 microcal/cm² sec) heat-flow, with a narrower band (about 100-200 km wide) of very high (more than 3 microcal/cm² sec) heat flow at the crest. Low seismic  $P_n$  velocities have been observed associated with the crest<sup>9</sup>. Menard<sup>25</sup> suggests that this crest enters the continent through the Gulf of California; this is strongly supported by the extremely high heat flows observed in the Gulf<sup>18</sup>. The continental continuation is not clearly delineated, but it is generally accepted<sup>22,24</sup> that the crest leaves the continent at about latitude 40° N. and continues as shown in Fig. 1. This assumed continuation is based primarily on the distribution of shallow earthquakes, without definite confirmation by high heat flow observations. Recent work on earthquakes off western Canada<sup>26</sup> indicates that the distribution of maximum strain-energy release (rather than the frequency of occurrence) runs closer to Vancouver Island. It is therefore possible that the 'crest' is located further east—perhaps even as far as the arc of recent and Pleistocene volcanoes which parallels the west coast about 150 km inland<sup>26</sup>. This suggestion is based on the admittedly tenuous assumptions that: (a) the continental

continuation of the East Pacific rise is delineated by the geomagnetic low- $I$  and seismic low  $P_n$ -velocity zone; (b) the 'crest' (here defined as the narrow band of very high heat flow) would be located near the centre of the rise. Due to the scarcity of continental heat flow data, this extrapolation of oceanic rise properties to its assumed continental continuation remains speculative. However, the proposed model shown in Fig. 2 is at least compatible with all the available geophysical information. The model is shown in detail with an expanded vertical scale, and also to scale in order to demonstrate the geometrical plausibility of the proposed upwelling. A discussion of the mechanisms responsible for the proposed isotherm upwelling is beyond the scope of this article, but the model is fully compatible with suggested mantle convection theories<sup>20,22,27</sup>.

Whatever the validity of some of the speculations presented in this article, it is clear that in some cases geomagnetic depth-sounding can serve as a powerful tool for upper mantle research, provided that its limitations are recognized and that it is used in conjunction with other geophysical methods. Even though it cannot provide a unique interpretation, it can impose useful restraints on choice of

models as well as geographical delineation of anomalous zones. Surveys in the different branches (seismology, geomagnetism, magneto-tellurics, heat-flow) will be carried out in western Canada over the next few years by various Government and university research groups. Although there is as yet little active co-ordination between the different disciplines, the sum total of the data which will become available should permit verification of our hypothesis in so far as western Canada is concerned. Some geomagnetic depth-sounding will also be carried out in New Mexico by the Department of Geophysics of the University of British Columbia, to investigate a suggestion made by Slawson (private communication) that the geomagnetic anomalies of Schmucker<sup>3</sup> may correlate with a pattern of lead isotope abundances<sup>28</sup>. Since very good seismic control is available for this region, the proposed correlation should be easy to verify.

A major uncertainty is presented by the region between latitude 36° and 46° N.; at present the low  $P_n$  velocities are the only support for our assumption of a continuous structure (rather than just two localized upwellings, in the south-western United States and in western Canada). Further work in this region will be required to verify this assumption.

We thank Dr. J. A. Jacobs, head of the Department of Geophysics in the University of British Columbia, for his support, Dr. W. G. Milne and Dr. W. R. H. White, of the Observatory's Division of Seismology at Victoria, for their advice, and Dr. A. M. Jessop, of the Dominion Observatory, Ottawa, for supplying unpublished heat-flow data. This work has been supported by the National Research Council of Canada.

## LAYERING IN THE GALWAY GRANITE

By J. W. AUCOTT

Department of Geology, University of Bristol

THE Galway Granite, western Ireland, is about 400 square miles in extent and is intruded into acid and basic migmatites and Dalradian metasediments. According to Giletti, Moorbatch and Lambert<sup>1</sup> the last major metamorphism of the Dalradian was 470 m.y. while the age of the Galway Granite is given as 365 m.y.; thus it is about Middle Devonian.

The present investigation in the Slieve Moidaun area between Invermore and Carna was started during the summer of 1963 and several mappable granite types were recognized, but no contacts between the different granites were found. The commonest granite consists of a rather variable porphyritic adamellite which is similar to the Errisbeg Townland Granite of Wager<sup>2</sup>. From the coast, this extends about 2 miles northwards towards the contact with the migmatites, but between a quarter and half a mile from the contact the phenocrysts diminish in size and eventually disappear. This non-porphyritic granite resembles, both in chemical composition and texture, the Murvey Granite also described by Wager<sup>2</sup>, though it may contain a little more biotite. When traced westwards near the contact this granite merges into a lighter, biotite-poor granite which is similar to the Garnetiferous Murvey Granite of Murvey, except that it is slightly coarser and does not contain garnets. The transition zone is about 100 ft. wide.

During the summer of 1964 a portable scintillation rate-meter (Type 1418A) was used to survey the gamma-radiation of the area. This has a 1½-in.-diameter 1-in.-thick thallium-activated sodium iodide crystal coupled to an E.M.I. photomultiplier tube. The meter is of the direct-reading type and is calibrated against natural radium. There are four scales to read from; the one most used when working on granites gives a full-scale deflexion of 0.060 mr./h. The instrument is fully transistorized and runs off three 1.5-V batteries and weighs about 9.25 lb. It is easily carried in a rucksack.

When using the instrument, a base station is set up and a routine check, which includes background, is carried out twice daily, the first reading in the morning and the last reading at night. The values are averaged and the field readings adjusted accordingly. During June–September the base station readings varied between 0.010 and 0.012 mr./h. Some field positions were checked three or more times on different days; the greatest variation was 0.001 mr./h. In Fig. 1, the values quoted included cosmic radiation as well. This is 0.003 mr./h when it is measured over deep open water. When taking field measurements the scintillation counter was placed on an open, lichen-free, rain-washed rock surface, which was as flat as possible. No readings were taken in hollows or gullies, or on narrow ridges, as anomalous values would have been obtained due to the solid-angle effect. The instrument is very sensitive and will differentiate between gamma-radiation from localities as close as 3–4 ft. When taking readings at each station there was a random fluctuation which, at its worst, was  $\pm 0.005$  mr./h. If fluctuations were great, three or more readings were taken at the one station and the values

averaged. During this radiometric survey, over continuous exposures a 100-yd. grid was maintained where possible, except when contacts were present and closer readings were taken.

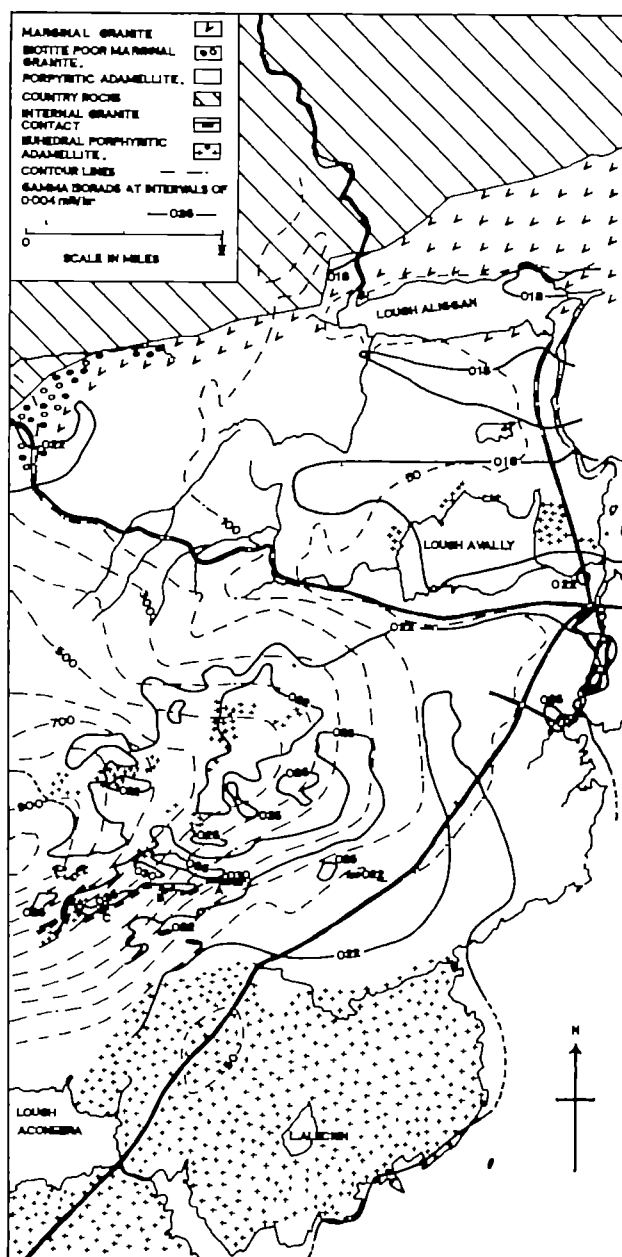

Fig. 1. Geological sketch map, showing the relationship between geology, activity, and topography

A gamma-isorad map is shown in Fig. 1. The contours are drawn ignoring the faults, as it is difficult to estimate displacements within a granite. It can be seen that values range from 0.014 to 0.032 mr./h in the granite.

Slieve Moidaun rises to just more than 1,000 ft. and extends parallel to the coast in an east-north-easterly direction. To the north and south of Slieve Moidaun the isorads are wide apart, while to the east they sweep around the hill. The steeper face shows the isorads to be set very close together, and generally trending east-north-east to west-south-west and consisting of a series of highs and lows. To explain the geometry of the isorad map, coupled with field evidence, it is proposed that the granite is disposed in layers which dip to the north or north-west. The north to south isorad anomaly west of Lough Alligean near the contact coincides with the transition between the two types of Murvey-like granite.

The granite exposed on Slieve Moidaun and on the coastal flat to the south is usually a porphyritic adamellite varying from a coarse-grained good porphyritic adamellite with euhedral potash feldspar phenocrysts to a poorly porphyritic adamellite with subhedral phenocrysts. Sometimes the adamellite is coarse grained and non-porphyritic. The layered disposition of the granite is shown by the wider, more uniform nature of the rock when exposed on the coastal flat south of Slieve Moidaun and on the low dipping north side. The steep south face of Slieve Moidaun shows the widest variety of granite types as exposed in 'strike' section. There is a distinct zone varying between 10 and 60 ft. thick where the porphyritic adamellite diminishes in grain size, upwards, becoming granitic and often aplitic and showing a sharp contact with normal coarse-grained adamellite above it. The contact is considered to be unchilled and can be traced for more than 0.25 mile. Biotite layers may occur along this contact and when seen they strike north-east to south-west and dip north-west. Biotite layers are common in the adamellite and also strike north-east to south-west with a dip which varies from 10° to 50° north-west. Some of the biotite layers show crystal settling with sharp bases grading upwards into more felsic material. The biotite layers may also cut one another similar to the mafic layering in the Alangorssuaq area in Greenland, as described by Harry and Emelius<sup>4</sup>. Basic xenoliths occur throughout the area and their long axes trend north-east to south-west or east-west dipping either vertically or northwards towards the contact. The contact between the finer granite and the overlying coarse adamellite dips north-west between 5° and 25°, and is always sharp. It is usually straight, but in some places small irregular lobes protrude upwards into the coarse adamellite. This contact is consistent along the length so far examined, with the granite above always consisting of a coarse-grained inequigranular hypidiomorphic adamellite with subhedral

to euhedral potash feldspar phenocrysts. In one or two localities the potassium feldspar phenocrysts are orientated parallel to the contact just below. A slight foliation may also be developed in the adamellite above the contact.

Below the contact, the granite is fine-grained, sometimes granophyric, increasing in grain-size downwards until the normal porphyritic adamellite is reached. This zone, in which the transition occurs between the porphyritic adamellite and the contact, is variable in thickness. At point A it is 70 ft., at point B it is 20 ft., while at point C the only evidence of the transition and contact is a 3-in. band of fine-grained granite in the porphyritic adamellite. The top of the zone is always sharp with the porphyritic adamellite above, but the granite below can also consist of a layered zone up to 20 ft. thick, consisting of fine- and coarse-grained granite intermingling. Because of the variability of the zone below the contact as regards the thickness of the finer-grained granite, the layers are thought to be lensoidal. This is supported to a certain extent by the radiometric evidence as the gamma-isorads close as they are traced along the strike. Above the contact differently textured porphyritic adamellites strike east-north-east and several zones of porphyritic adamellite with good euhedral potash feldspar phenocrysts merge laterally into a porphyritic adamellite with anhedral phenocrysts.

The radiometric evidence and the field evidence suggest that the porphyritic adamellite is layered and is not a uniform granite as it has been considered. Possible minor differentiating cycles in the sequence could be indicated by the increase of gamma-radiation from 0.024 mr./h in the adamellite to 0.032 mr./h in the more acid granite just below the contact with the overlying adamellite. This adamellite gives a much lower reading of 0.026–0.028 mr./h.

The layered nature of the intrusion is indicated by the work of Wright<sup>5</sup>, who mapped five distinct granite types in the Carna area, just to the west of the present investigation. He indicated that the various granite types were intruded as sub-horizontal lacoliths which also dip northwards towards the contact with the country rocks. Further geochemical work is being undertaken, the radiometric survey is being extended westwards and it is hoped to present more information in due course.

I thank Mr. S. H. U. Bowie and the Atomic Energy Division of the United Kingdom Geological Survey for suggesting the radiometric survey and the loan of the rate-meter, Dr. B. E. Loake and Mr. I. H. Ford for advice, and the Department of Scientific and Industrial Research (now the Science Research Council) for a research grant.

## EVOLUTION OF THE OCEANS AND THE ORIGIN OF FINE-GRAINED DOLOMITES

By PROF. JON N. WEBER

Department of Geochemistry and Mineralogy, Pennsylvania State University, Pennsylvania

CONTROVERSY has arisen concerning the origin of certain fine-grained, so-called 'primary' dolomites which are widespread in nature<sup>1</sup>. One of the major questions involved is whether the dolomite precipitated directly from sea-water or instead replaced sediments composed of calcium carbonate. Much geological evidence suggests direct chemical precipitation in marine evaporite basins, yet no one has been able to demonstrate experi-

mentally such a process, and modern sediments comparable to the extensive strata of high-purity dolomite have not been observed. If, on the other hand, the dolomite is a diagenetic replacement of pre-existing calcite, the cause and the mechanism of the alteration process remain to be explained.

Recently, some very important work of Epstein *et al.*<sup>2</sup> has opened up a new approach to the problem. Hydro-

thermal experiments by those authors, and isotopic analyses of high-temperature, natural quartz-calcite and quartz-dolomite pairs by Clayton and Epstein<sup>8</sup>, indicate that isotopic equilibration of calcite and dolomite at Earth surface temperatures should result in oxygen-18 enrichment in dolomite (with respect to the coexisting calcite) of 5–8 per mil<sup>4</sup>. Even under hydrothermal conditions, dolomite is difficult to crystallize, and Epstein *et al.* concluded that in some experiments calcite formed first. This mineral was then replaced by dolomite by some mechanism in which magnesium was incorporated in the solid phase without alteration of the  $^{18}\text{O}/^{16}\text{O}$  ratio of the carbonate ion of the original calcite. The bearing on the dolomite problem is immediately obvious; if the explanation of the experimental data is valid, and if natural 'dolostones' were formed by diagenetic replacement of pre-existing calcite, then examination of sedimentary rocks containing coexisting calcite and dolomite should show no fractionation of oxygen isotopes between these two minerals. Thus a good case for secondary dolomite might be established.

However, if dolomite were found to have a higher  $^{18}\text{O}/^{16}\text{O}$  ratio than coexisting calcite, could this observation be used as proof for primary chemical precipitation of the dolomite? Unfortunately, the answer is negative since such results cannot be interpreted uniquely. Possible explanations are: (1) the dolomite is primary and both calcite and dolomite were precipitated in isotopic equilibrium with sea-water; (2) the dolomite is a late diagenetic replacement product, but during dolomitization, isotopic equilibration occurred; (3) the dolomite formed authigenically very soon after deposition of the calcite, before lithification, and the slow authigenic alteration of calcite permitted isotopic equilibration (that is, replacement may have involved a solution-recrystallization mechanism rather than one of solid-state diffusion); (4) dolomite replaced pre-existing calcite without any change in the  $^{18}\text{O}/^{16}\text{O}$  ratio, but subsequent contact with intrastratal fluids and formation waters (usually enriched with oxygen-18) involved exchange of oxygen isotopes with calcite but not with the less-soluble and less-reactive dolomite. Each of these explanations could account for oxygen-18 enrichment of dolomite with respect to calcite in ancient sedimentary rocks. Before reviewing data available at the present time concerning  $\delta^{18}\text{O}_{\text{calc}}$  and  $\delta^{18}\text{O}_{\text{dol}}$  and before evaluating each of these hypotheses, a further complication requires some discussion: has the  $^{18}\text{O}/^{16}\text{O}$  ratio for sea-water changed with time?

The precipitation of both silica and calcium carbonate from sea-water involves fractionation of the oxygen isotopes so that the solid phase is enriched in oxygen-18. Silverman<sup>9</sup> noted that there is a net accumulation of these deposits with time, and thus as oxygen-18 is preferentially extracted from sea-water in calcareous sediments and chert, the  $^{18}\text{O}/^{16}\text{O}$  ratio of sea-water must have decreased with time, so that the  $^{18}\text{O}/^{16}\text{O}$  ratio of the present oceans is lower than that of Cambrian sea-water. Degens<sup>6</sup> and others have expanded this argument.

I have criticized<sup>7</sup> this hypothesis on the basis of evidence to be discussed later, and have proposed the argument that the  $^{18}\text{O}/^{16}\text{O}$  ratio of sea-water has increased with time. If the oceans have evolved by degassing of the Earth throughout geological history<sup>8</sup>, the addition of juvenile water to the oceans may have influenced the isotopic composition of sea-water. Juvenile or magmatic water is extremely elusive, and both the rate of escape from the Earth's interior and the isotopic composition are difficult to determine. Using the most reliable estimates<sup>7</sup> it is possible to construct a mass balance equation whereby the oxygen-18 content of the present oceans must equal that of the ancient oceans, less the oxygen-18 extracted by carbonate and non-detrital siliceous sediments, plus the oxygen-18 added by juvenile water. Imprecision of the estimates involved does not permit calculation of the  $^{18}\text{O}/^{16}\text{O}$  ratio of Cambrian sea-water, but it is found

that the estimated oxygen-18 contribution of juvenile water is of sufficient magnitude to influence the  $^{18}\text{O}/^{16}\text{O}$  ratio of sea-water.

There are, therefore, two opposing hypotheses concerning the oxygen isotopic composition of ancient sea-water. It will be shown that  $\delta^{18}\text{O}$  analyses of coexisting calcite-dolomite pairs in sedimentary rocks may be used to investigate further this problem.

(1) *Calcareous limestones.* It has been known for some time that the older carbonate rocks are relatively enriched in oxygen-18. Variation of the  $^{18}\text{O}/^{16}\text{O}_{\text{calc}}$  ratio with time was suggested by the early analyses<sup>8</sup>, but the trend was not well defined until a large number of rocks had been analysed. Keith and Weber<sup>10</sup> reported  $\delta^{18}\text{O}$  analyses for more than 500 specimens ranging in age from Cambrian to the present. These samples varied widely in geographic locality, and since the depositional environment exerts some influence on the  $^{18}\text{O}/^{16}\text{O}$  ratio of the carbonate, only limestones containing marine fossils were included. Mean values for each age category are: (Precambrian, -11.39); Cambrian, -9.72; Lower Palaeozoic, -8.65; Upper Palaeozoic, -4.95; Jurassic, -4.98; Cretaceous, -4.18; Tertiary, -2.33; Quaternary, -1.18, relative to the PDB standard  $\text{CO}_2$  (expressed as the oxygen-18 difference, in parts per mil, between the sample and the PDB standard carbon dioxide by the relation:

$$\delta^{18}\text{O} = \left( \frac{^{18}\text{O}/^{16}\text{O}_{\text{sample}} - ^{18}\text{O}/^{16}\text{O}_{\text{std}}}{^{18}\text{O}/^{16}\text{O}_{\text{std}}} \right) 1,000$$

Three explanations might be advanced to account for these data: (i) Since the fractionation factor,  $\alpha = [^{18}\text{O}/^{16}\text{O}_{\text{H}_2\text{O}}]/[^{18}\text{O}/^{16}\text{O}_{\text{calc}}]$ , is temperature dependent, a change in the mean annual temperature of sea-water may be responsible. The inadequacy of this explanation is immediately evident since temperatures calculated from the  $^{18}\text{O}/^{16}\text{O}$  ratio of Cambrian carbonates are much above the maximum temperature tolerated by living organisms. (ii) Sea-water has become enriched in oxygen-18 with time by the addition of juvenile water. (iii) Ancient calcites have partially equilibrated with formation waters, and the degree to which oxygen isotopes have reached a state of equilibrium is more or less a function of the age of the limestone.

(2) *Dolomitic limestones.* Degens and Epstein<sup>11</sup> examined a "wide range of carbonate specimens representing a variety of genetic types", and "care was taken that the selection included representative dolomites of recent and ancient, continental and marine, and synsedimentary and late diagenic origin". Their results for ancient rocks indicate that dolomite is enriched with oxygen-18 with respect to coexisting calcite, but the data are too few to demonstrate that  $\delta^{18}\text{O}_{\text{dol}}$  is proportional to the age of the sample, or that  $\delta^{18}\text{O}_{\text{dol}} - \delta^{18}\text{O}_{\text{calc}}$  varies with time. On the basis of the hydrothermal experiments of Epstein *et al.*, and the fact that Degens and Epstein observed no fractionation of oxygen isotopes between calcite and dolomite from relatively recent sediments in the Bahamas, Florida and the Coorong of Australia, Degens and Epstein concluded that: (a) all dolomites are derived by metasomatic replacement of calcite or aragonite; (b) ancient calcite is depleted in oxygen-18 with respect to associated dolomite because of oxygen isotope equilibration of the calcite with sub-surface waters.

The argument that observed differences in the  $^{18}\text{O}/^{16}\text{O}$  ratio of ancient coexisting calcite and dolomite are evidence of primary precipitation of the dolomite can probably be dismissed on the grounds that this hypothesis contradicts an enormous amount of experimental work directed toward precipitating dolomite from solution under conditions encompassing those in Nature. The alternatives are: (1) equilibration of dolomite, calcite and fluid occurred during dolomitization, or (2) dolomitization occurred without alteration of the  $^{18}\text{O}/^{16}\text{O}$  ratio, but the calcite later exchanged oxygen isotopes with sub-surface water.

In the first case, the  $\delta^{18}\text{O}_{\text{ct}}$  and  $\delta^{18}\text{O}_{\text{dol}}$  would be equilibrium values; in the latter they may not.

I suggest that the dolomite and calcite may have differed in isotopic composition before lithification, at least so far as the fine-grained, so-called "syngenetic dolomitic limestones" are concerned, and that subsequent equilibration with formation waters is not a major factor. One approach to this problem is the examination of fine-grained dolomitic limestones of freshwater origin. If the interpretation of Degens and Epstein is correct, then dolomite replacing freshwater calcite should have an isotopic composition similar to modern or Tertiary freshwater calcites. Associated calcite would be relatively enriched in oxygen-18 if equilibration with sub-surface waters took place. If, on the other hand, such dolomites show  $\delta^{18}\text{O}/\delta^{16}\text{O}$  ratios significantly higher than modern freshwater calcites, early equilibration of calcite and dolomite might be indicated. Two such freshwater deposits have been studied: the Palaeocene-Eocene Flagstaff formation<sup>11</sup> (central Utah) where  $\delta^{18}\text{O}_{\text{ct}} = -9$  to  $-10$  per mil, and  $\delta^{18}\text{O}_{\text{dol}} = -3$  to  $-4$  per mil, and the Upper Carboniferous Freeport formation<sup>12</sup> (central Pennsylvania), where  $\delta^{18}\text{O}_{\text{ct}} = -7.87$  per mil, and  $\delta^{18}\text{O}_{\text{dol}} = -3.04$  per mil. These values may be compared with  $\delta^{18}\text{O}$  analyses of eleven freshwater calcium carbonates of Quaternary age<sup>10</sup> (mean  $-8.15$  per mil, standard deviation  $2.08$ ) and  $63$  of Tertiary age (mean  $-9.65$ , *S.D.*  $4.48$ ). The data are difficult to acquire and are therefore few in number at the present time. There is insufficient information to characterize variation or 'noise', and the influence of possible variation of the  $^{18}\text{O}/^{16}\text{O}$  ratio of sea-water with time must be taken into account since the oxygen-18 content of freshwater is to some extent related in the oxygen-18 content of the oceans. The preliminary data appear encouraging and further investigation is warranted.

The fundamental questions are: (1) Has the  $^{18}\text{O}/^{16}\text{O}$  ratio of sea-water changed with time or not? (2) Is oxygen-isotope equilibration of dolomite and calcite in "syngenetic limestones" common or not? (3) Is post-depositional oxygen-isotope equilibration of calcite and sub-surface water a common phenomenon or not? With sufficient data some of these questions may be answered. Models for the three major cases may be constructed (see Figs. 1-3). In Fig. 1, the  $^{18}\text{O}/^{16}\text{O}$  ratio of sea-water is assumed to have increased with time, according to the hypothesis of Weber<sup>1</sup>. Two extreme sub-cases involve 'early syngenetic' dolomitization and late diagenetic dolomitization; there appear to be petrographical and lithological criteria to distinguish these varieties in many cases. For each sub-case, there are two further possibilities: either  $^{18}\text{O}/^{16}\text{O}$

Fig. 1. Generalized models predicting the oxygen isotopic composition for coexisting calcite and dolomite in marine carbonates if the  $^{18}\text{O}/^{16}\text{O}$  of sea-water has increased with time. Dashed line in each model represents the  $\delta^{18}\text{O}$  value of modern marine calcites. The extremes on the time-scale represent Cambrian at the left and Recent on the right.

Fig. 2. Generalized models, similar to Fig. 1, where the  $^{18}\text{O}/^{16}\text{O}$  ratio of sea-water has been assumed to decrease with time.

Fig. 3. Generalized models, similar to Fig. 1, where the  $^{18}\text{O}/^{16}\text{O}$  ratio of sea-water is assumed essentially constant from the Cambrian to the present.

exchange between calcite and formation waters was substantial, or it was not.

Fig. 2 represents analogous categories in Case II, where the  $^{18}\text{O}/^{16}\text{O}$  ratio of sea-water is assumed to have decreased with time, according to the hypothesis of Silverman<sup>8</sup>, Degens<sup>9</sup> and others. Case III, shown in Fig. 3, is included for completeness; the  $^{18}\text{O}/^{16}\text{O}$  ratio of sea-water is assumed to have remained constant. It is possible, of course, that major changes in the isotopic composition of the oceans may be cyclic or even random, but no evidence of this has appeared and no hypotheses concerning such phenomena have been advanced. In each model, the dashed line represents the isotopic composition of modern marine calcites.

In model *a* (Fig. 1), calcite has been precipitated from sea-water becoming increasingly enriched in oxygen-18. Syngenetic dolomite is heavier than the associated calcite and its isotopic composition is represented by a line located above that for calcite. Originally the two lines would have been parallel. Oxygen isotope exchange between sub-surface water and calcite, however, will shift the slope of the line so that  $\delta^{18}\text{O}_{\text{dol}} - \delta^{18}\text{O}_{\text{ct}}$  is greater for more ancient carbonates, assuming that the extent of equilibration is proportional to the time available for the process.

Model *c* is equivalent to model *a* except that equilibration of calcite and formation waters has not been significant.

In model *e*, ancient calcite was enriched with oxygen-18 with respect to later calcites. Dolomite was enriched with oxygen-18 with respect to the associated calcite. Equili-

bration of calcite with sub-surface water would shift the line representing the  $\delta^{18}\text{O}$  of calcite to a position somewhere within the zigzag area. Model *g* is identical with *e* except that the calcite isotopic composition has remained unaltered since deposition.

If sea-water  $^{18}\text{O}/^{16}\text{O}$  has remained constant (Fig. 3),  $\delta^{18}\text{O}_{\text{dol}}$  should be greater than  $\delta^{18}\text{O}_{\text{ct}}$ , but neither should vary with time if equilibration of fluids and calcite is insignificant (model *k*). With oxygen-18 - oxygen-16 exchange between sub-surface water and calcite,  $\delta^{18}\text{O}$  for ancient calcites should be less than that for more recent specimens, but  $\delta^{18}\text{O}_{\text{dol}}$  would remain unchanged (model *i*).

Similar arguments can be applied to situations where dolomitization occurred without alteration of the  $^{18}\text{O}/^{16}\text{O}$  ratio of the calcite, as proposed by Degens and Epstein. In Case I, where the  $^{18}\text{O}/^{16}\text{O}$  ratio of sea-water has increased with time, the line representing the  $\delta^{18}\text{O}$  of calcite slopes to the left. With no post-depositional oxygen isotope exchange between calcite and sub-surface water (model *d*)  $\delta^{18}\text{O}_{\text{ct}} - \delta^{18}\text{O}_{\text{dol}} = \text{zero}$  for coexisting pairs. With equilibration (model *b*), the isotopic composition of the dolomite will vary much more than that of the calcite, since the value of  $\delta^{18}\text{O}_{\text{dol}}$  depends not only on the age of the calcite but also on the length of the time-interval between precipitation of the calcite and dolomitization. For example, if dolomitization of a Cambrian limestone occurred soon after lithification,  $\delta^{18}\text{O}_{\text{dol}}$  would be similar to the isotopic composition of calcites in Cambrian time. If dolomitization of the same limestone occurred long after lithification, for example, in Mesozoic time, the  $^{18}\text{O}/^{16}\text{O}$  ratio of the dolomite would be much lower than that of the calcite in Cambrian time because in the time-interval separating the Cambrian from the Mesozoic, the calcite would have been enriched in oxygen-16 as a result of equilibration with sub-surface waters. With sufficient data, perhaps many hundreds of samples, variation about the line representing  $\delta^{18}\text{O}_{\text{dol}}$  should be significantly greater than variation about the line for  $\delta^{18}\text{O}_{\text{ct}}$ . This is repre-

sented by a zigzag curve in model *b*. With this explanation, models *f*, *h*, *j* and *l* require no further elucidation.

With present information, which models appear plausible? The trend of  $\delta^{18}\text{O}_{\text{ct}}$  with time is fairly well known from the analysis of more than 500 specimens of carefully selected limestones<sup>10</sup>. On this basis, models *g*, *h*, *k* and *l* are eliminated.

The isotopic data for coexisting calcite and dolomite from Degens and Epstein<sup>11</sup> indicate that for ancient dolomitic limestones,  $\delta^{18}\text{O}_{\text{dol}}$  is greater than  $\delta^{18}\text{O}_{\text{ct}}$ , and  $\delta^{18}\text{O}_{\text{dol}}$  is less than the  $\delta^{18}\text{O}_{\text{ct}}$  of modern marine calcites (dashed line, Figs. 1-3). Models *d*, *e*, *f*, *g*, *h*, *i*, *k* and *l* are therefore unlikely.

Remaining are models *a*, *b*, *c* and *j*. The available data are insufficient to evaluate further these models since background noise arising from other variables is high enough to camouflage any  $\delta^{18}\text{O}_{\text{dol}}$ -time trend.

Further investigation of 'syngenetic' dolomitic limestones may provide a basis for choosing one of the remaining models. If this is possible, the rewards are enormous; the use of oxygen isotope ratios for palaeotemperature determination and for environmental analysis may be extended far past the Mesozoic.

## NICKEL CONTENT OF PACIFIC OCEAN CORES

By PROF. FRANCIS T. BONNER\* and ALZIRA SOARES LOURENÇO†

Department of Chemistry, State University of New York at Stony Brook, Long Island, New York

HIGH nickel content in central Pacific sediment cores, relative to continental rocks and sediments, was reported by Pettersson and Rotschi<sup>1</sup>, who advanced the hypothesis that meteoritic dust settling on the Earth's surface is the origin of a nickel surplus. Their examination of three long cores indicated significant variation of nickel concentration with depth, but an abundance everywhere greater than the estimated average crustal value of 0.008 per cent<sup>2,3</sup>. Smales and Wiseman<sup>4</sup> concluded that meteoritic material contributes little to the content of deep-sea sediments, on the basis of comparisons of nickel-cobalt, nickel-copper and copper-cobalt ratios in Pacific red clays and in meteorites. Their interpretation of these ratios has been challenged by Öpik (as reported by Pettersson<sup>5</sup>). Extensive neutron activation investigations of terrestrial and oceanic rocks, marine sediments and meteorites<sup>6</sup> were taken to provide general apparent support to the findings of Smales and Wiseman but without elimination of possible local meteoritic influence. It was shown in 1958 that spherules magnetically separated from deep-sea sediments are similar in composition to iron meteorites<sup>7</sup>, although it had previously been reported that the content of magnetically separable spherules in a core of high nickel content

appeared too low to contribute significantly to the observed bulk content of that element<sup>8</sup>. Pettersson<sup>9,10</sup>, nevertheless, estimated a value for the rate of extra-terrestrial nickel accretion, on the basis of particles captured by atmospheric filtration at high altitude, which is within an order of magnitude of his previous estimate based on an assumed extra-terrestrial origin of nickel excess in deep-sea cores. Turekian<sup>11</sup> estimated an accretion rate similar to Pettersson's, by combining carbon-14 sedimentation rate data and nickel analyses for an Atlantic equatorial core. He does not consider this a corroboration of the extra-terrestrial origin hypothesis, however, on the ground that accumulation rates of other elements such as copper and lead were high in the particular core examined.

While strong evidence of cosmic origin for the magnetic spherules has accrued<sup>7,12,13</sup>, the origin of the apparent high-bulk nickel content of Pacific sediments seems to remain unresolved. There can be no doubt that a portion at least of this nickel is of terrestrial origin; but one could still assume an increment of nickel resulting from a steady influx and settling of fine cosmic dust, generally similar to meteorites in composition and either non-magnetic or, if magnetic, too small in particle size for efficient separation in the usual magnetic device. If such a dust does, in fact,

†Fellow of the Organization of American States, 1962-64.

contribute significantly to the content of pelagic sediments, broad correlations in nickel content between separate cores should be observable, although local meteoritic events would of course still be expected to cause local fluctuations. In the work recorded here profiles of nickel content of two Pacific cores have been obtained and compared.

Samples of the two deep-sea cores V18-306 (07° 20' S.; 133° 03' W.; depth 4,491 m) and V18-307 (08° 32' S.; 131° 57' W.; depth 4,711 m) were obtained from the Lamont Geological Observatory of Columbia University. The region involved is far removed from major land masses; we assume the rate of sedimentation to be low, probably of the order of millimetres per thousand years, as reported for another core taken at similar latitude<sup>13</sup>. The two cores were collected on successive days of the 1962 voyage of the *Verna* thus providing material from separate localities of the same general region. In addition to the core samples, sediment material dredged from the south Pacific ocean bottom has been made available to us.

Gross samples weighing 1–2 g were taken from regions centred about the positions of core depth chosen for analysis. These were leached to remove all water-soluble material. In order to achieve high sensitivity over a wide range of nickel concentration in small sizes of sample, the method of neutron activation analysis was used. The procedure applied was similar to that of Smiles *et al.*<sup>14</sup> in its wet chemical aspects, but included additional chromatographic and electrochemical stages. The usual sample size was 100 mg of dry sediment; each such sample, along with a 10-mg standard of spectroscopically pure nickel, was irradiated for 1 h at a flux of about  $10^{13}$  neutrons  $\text{cm}^{-2} \text{sec}^{-1}$  in the Brookhaven graphite reactor. After dissolving the sample and addition of inactive nickel and appropriate holdback carriers, radiochemical purification was achieved by successive precipitations of nickel dimethylglyoxime and manganese dioxide, passage in 9N hydrochloric acid through a 'Dowex LX-4' anion exchange column, and final preparation for counting by electro-deposition of the nickel on one side of a copper disk. Chemical yield was determined by the weight of nickel deposited. An aliquot of the irradiated nickel standard was simultaneously deposited on a separate copper disk, with carrier added so that standard and sample deposits were of approximately equal thickness. The quantities of  $^{60}\text{Ni}$   $\beta$  activity in standard and sample were compared by proportional counting, continued over several half-lives of the nuclide. In view of the close coincidence in the half-lives of  $^{60}\text{Ni}$  (2.56 h) and the possible contaminant nuclide

$^{54}\text{Mn}$  (2.58 h),  $\gamma$ -ray spectrometry was used to monitor the efficacy of manganese decontamination. Samples taken from regions of very high manganese concentration were found to require one or more additional  $\text{MnO}_2$  precipitations. Confidence in the analytical method was gained by its application to National Bureau of Standards basic open-hearth steel samples. Analyses were performed on whole sediment, with only water-soluble constituents removed. Inorganic carbonate content was determined separately. Assuming all carbonate present to be  $\text{CaCO}_3$ , the data have been corrected to a  $\text{CaCO}_3$ -free basis. Carbonate content was generally significant only in the uppermost layers of these cores.

The nickel concentration profiles obtained for the two cores are shown graphically in Fig. 1. Results of replicate analyses are shown in Fig. 1 for material at several depths. Although our experience with standard steels indicated a reproducibility to within about 2 per cent, there are several instances of greater dispersion in the results of replicate sediment sample analyses, as shown. Seven measurements on dredged sediment material gave a mean value of 270 p.p.m., with minimum and maximum values of 218 and 302 p.p.m. respectively. We believe that heterogeneity of the sediment materials, with respect to nickel, is strongly indicated.

Within the limitation already described here, we note the following features of the two profiles:

- (1) The observed nickel concentration is everywhere greater than the average crustal rock value<sup>3</sup> of 0.003 per cent, although at some points not significantly so; it is also nearly everywhere greater than the basalt average of 150 p.p.m. given by Taylor<sup>15</sup> from the data of Turekian<sup>14</sup>.
- (2) The values are in the same general range as those reported by Pettersson and Rotschi<sup>1</sup>.
- (3) Both cores exhibit broad maxima in the upper regions, that in 307 being more pronounced and somewhat displaced toward increased depth, with respect to 306.
- (4) In both cores the observed broad maxima are followed by broad minima again more pronounced in the case of 307.

The broad features described here may be considered consistent with the hypothesis of extra-terrestrial origin if one assumes a roughly constant influx of meteoritic nickel during the total period of sedimentation involved and a rate of total sedimentation that fluctuates with climatic conditions. Thus the higher nickel concentration of recent deposit, observed in both cores, may be attributable to a lowered rate of arrival of sediment of continental origin in this region during recent glaciation. This is at variance with the view expressed by Turekian<sup>11</sup> that terrestrial control of supply is indicated by climatic variation in the rate of accumulation of nickel. The sedimentation rates in the Atlantic equatorial core he investigated are very large, however, and the average nickel contents exceedingly low. Under these conditions the measurements may well have lacked sensitivity to any possible increment above the undisputed terrestrial supply. Accounts of single 'average' values over extended intervals of core material may be misleading in the search for an incremental concentration, particularly when the values are as low (18 and 17 p.p.m.) as those reported<sup>11</sup>. Finally, given the high gross sedimentation rates involved, we do not believe Turekian's observation of high rates of accumulation of copper and lead to be necessarily meaningful to the question at issue.

Assuming the top 200 cm of the cores investigated here to represent a total time span of  $10^4$  years, and an average of 200 p.p.m. of total nickel to be in excess of normal terrestrial supply, we estimate an annual accumulation of extra-terrestrial nickel for the Earth as a whole of  $4 \times 10^{11}$  g. This value, based on a generous allowance for nickel of terrestrial origin, is in agreement with the estimate of Pettersson<sup>1</sup> of  $3.5 \times 10^{11}$  g based on atmospheric particle collection. Our evidence of heterogeneity in nickel concentration supports the idea that at least some of the high

Fig. 1

nickel content found in these cores is present in particulate form.

Our observations do not constitute a 'proof' in any sense of the hypothesis of extra-terrestrial origin of a nickel surplus in deep-sea cores. We do maintain that the observed broad consonance in nickel concentration profiles in two cores, separate in space within a region far removed from major land masses in which the rate of sedimentation has been low, is consistent with that hypothesis, and that the question cannot be regarded as settled. Correlations between cores, as in the present investigation, co-ordinated with measurements of rates of sedimentation should assist materially in further pursuit of the issue.

We thank Prof. Maurice Ewing for making the deep-sea core materials available to us; the Brookhaven National

Laboratory for providing reactor irradiation services; Dr. D. R. Christman for carbonate analyses; and Dr. O. A. Schaeffer for his advice.

## DISTRIBUTION OF NEWLY FORMED SOLUBLE SULPHATE DURING THE FIRING OF A RADIOACTIVE-LABELLED BRICK

By DR. R. A. LLOYD and D. B. REES-EVANS

Department of Scientific and Industrial Research Radioisotope Applications Unit, Wantage, Berkshire

AND

I. L. FREEMAN and L. W. BALDWIN

Building Research Station, Garston, Watford, Hertfordshire

IT has recently been shown that during the firing of a high-sulphate building brick, considerable redistribution of sulphate occurs<sup>1</sup>. The brick was made artificially high in sulphate by incorporating  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$  labelled with sulphur-35 in the unfired clay, which was a Weald clay containing some organic matter and sulphide. It was remarked that the redistribution was surprising in view of the fact that calcium sulphate is relatively insoluble and thermally stable; hence one would not expect sulphate migration to occur during the drying of the moist clay, nor any appreciable thermal breakdown to occur at the firing temperatures used. The results showed that there was a loss of activity to the atmosphere during firing, presumably from the formation of gaseous sulphur oxides. Also, the redistribution of labelled sulphate occurred in such a way that the centre of the brick was almost devoid of sulphate, whereas just below the surface the peak concentration exceeded the original mean concentration of sulphate put into the clay. This was taken as evidence for a zone of re-concentration of sulphate just below the surface, for such a distribution cannot be obtained simply by a loss of active gaseous sulphur, in whatever chemical form it may exist.

The assays of water-soluble sulphate were both made radiometrically and gravimetrically, and it was noted that there was some discrepancy near the peak of the distribution curve. This has now been shown to be due to oxidation of sulphide in the unfired clay, with the consequent formation of new soluble sulphate. This newly formed soluble sulphate does not affect the radiometric assay, but obviously increases the gravimetric assay, and hence caused the puzzling drop in specific activity which had already been noted.

The results shown in Fig. 1 were obtained from samples taken from the brick 31 days after manufacture. The samples were taken from drillings normal to the  $8\frac{1}{2}$  in.  $\times$   $2\frac{1}{4}$  in. face and passing through the central plane  $2\frac{1}{4}$  in. from the surface. The upper curve shows the variation in total water-soluble sulphate assayed gravimetrically by barium sulphate precipitation. The peak in this curve occurs slightly more than 0.5 in. below the surface, and its level is far in excess of the mean concentration of labelled sulphate added to the unfired clay. The intermediate curve shows the variation in water-soluble radioactive

Fig. 1. The variation of soluble sulphate concentration in a fired building brick. Labelled  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$  was added to the unfired clay, which was otherwise free from soluble  $\text{SO}_3$ . The insoluble  $\text{SO}_3$  content (presumably as  $\text{FeS}_2$ ) was about 1 per cent before firing, but negligible afterwards. The newly formed soluble  $\text{SO}_3$  has a distribution as shown by the lowest curve, and an integrated mean level of about 1 per cent

sulphate assayed radiometrically by a liquid scintillation counting technique<sup>2</sup>. The peak is slightly nearer the surface (0.5 in.) and is approximately at the same level as the incorporated radioactive sulphate. (The initial sampling immediately after firing the brick showed that this peak had exceeded the level of added radioactive sulphate.) The two upper curves are widely divergent near their peaks but agree reasonably well near the central plane, which indicates that the divergence is not due to systematic errors in analysis. The lower curve is obtained by taking the difference between the two upper curves, and must represent newly formed sulphate which has appeared during the firing of the brick. This also shows a peak about 0.5 in. below the surface, and is practically zero at the centre of the brick. This non-radioactive sulphate was not present in the original unfired clay, which had a water-soluble sulphate content of 0.07 per cent as  $\text{SO}_3$ .

It was presumed that the source of the newly formed sulphate was insoluble sulphide present in the unfired clay, and subsequent analysis has proved this to be correct. The unfired clay was assayed in both our laboratories for total sulphur by four different methods; peroxide fusion, carbonate nitrate fusion,  $\text{Br}/\text{CCl}_4/\text{HNO}_3$  oxidation and  $\text{Br}/\text{H}_2\text{O}/\text{HCl}$  oxidation. The mean total sulphur content was 1.06 per cent as  $\text{SO}_3$ . In the fired brick, most of the sulphur was present as soluble sulphate, the residual insoluble sulphur content being only  $0.11 \pm 0.04$  per cent as  $\text{SO}_3$ , of which  $40 \pm 11$  per cent was radioactive. Hence the total sulphur available for oxidation was  $1.06 - 0.07 = 0.99$  per cent as  $\text{SO}_3$ . The mean level of newly formed sulphate, obtained by numerical integration throughout the volume of the brick, was 1.06 per cent as  $\text{SO}_3$ , which is in reasonable agreement. This has been confirmed by analysis of a further series of drillings from the radioactive brick and by measurements on non-radioactive bricks constructed in an identical manner.

It is reasonably certain that the sulphur in the unfired clay exists as some form of the very insoluble sulphide  $\text{FeS}_2$ , for the acid volatile sulphide content is very low. If all the iron sulphide had uniformly oxidized to sulphate the constant level throughout the brick would have been 1.06 per cent as  $\text{SO}_3$ , whereas in fact there is a peak of newly formed sulphate which exceeds this by about 30 per cent. These results show that the newly formed sulphate

behaves in a similar manner to the incorporated sulphate, and supports the former conclusion that there is a zone of sulphate reconcentration just below the surface of the brick.

The mechanism whereby sulphate is broken down and formed during the firing of the brick is still a matter for conjecture. The brick, for example, can be regarded as an inert porous matrix in which the following series of solid-state reactions are possible:

The sulphate  $\rightarrow$  sulphide part of the reaction if it exists is very small, because of the low residual sulphide content. The sulphate  $\rightarrow$  oxide part of the reaction and the oxide  $\rightarrow$  sulphate part do not necessarily occur at the same site; the latter reaction could well be responsible for the zone of reconcentration just below the surface.

It is still not clear why, in the centre of the brick, both sulphide and sulphate disappear, for the first requires oxidizing conditions while the second is known to require reducing conditions. (Gypsum heated in a reducing atmosphere with silica and alumina is a commercial source of  $\text{SO}_2$ .) It is possible, of course, that the two reactions are not independent. For example, the dissociation temperature of sulphate is lowered by the presence of  $\text{SiO}_2$  or  $\text{Fe}_2\text{O}_3$  (ref. 3) and presumably the dissociation temperature of  $\text{CaSO}_4$  could be lowered by the presence of  $\text{FeSO}_4$ . Another possibility is that the heated sulphide eliminates sulphur in the elemental form, which afterwards oxidizes after diffusion nearer to the surface. A further possibility is the formation of hydrogen sulphide by reaction of the heated sulphide with water from the clay mineral; there is an unmistakable smell of hydrogen sulphide from the centre of the freshly opened brick. However, apart from the mechanisms of the reaction, it is now apparent that newly formed sulphate distributes itself in the same way as added sulphate.

## ELECTRICAL POTENTIAL AT AN OIL/WATER INTERFACE

By GIUSEPPE COLACICCO\*

American-Standard Research Division, New Brunswick, New Jersey

MANY reports are available<sup>1</sup> about the electrical potential of the oil membrane, which consists of an 'oil' (pentanol, nitrobenzene, etc.) between two water layers; very little, however, is known about the nature of the potential. The importance long attached to the oil/water interface as a model system of biological interest is especially obvious when the oil contains, or is in contact with, biologically important materials such as phospholipids<sup>2</sup>, proteins and others.

The extensive work on the oil/water potentials culminated in the controversy between Beutner and Baur. Beutner<sup>3</sup> maintained that the electrical potential is generated by a partition equilibrium of the ions between oil and water; Baur<sup>4</sup> held that the observed potentials are produced by the selective adsorption of the ions into a double layer at the oil/water interface. Notwithstanding Baur's admission that Beutner was right and the assurance given by Adam that really both parties were right in the

circumstances<sup>5</sup>, the conceptual differences between the two points of view remain so powerful as to prompt re-investigation of the problem.

In the accepted approach<sup>3</sup>, the electrical potential of the oil cell was a function of the diffusion of the ions (small<sup>6</sup> and large<sup>1</sup>) under a concentration gradient and was described variously as a diffusion<sup>6</sup>, concentration or distribution potential by the Nernst and Henderson equations, which are still being used<sup>1,6</sup>. On the other hand, the simplified  $\Delta V$ -log  $c$  plot of the Gouy equation<sup>7,8</sup> for charged monolayers carries the limitations of the Gouy potential, which is restricted to the ideal (monovalent  $\text{NaCl}$ ,  $\text{KCl}$ ) dilute electrolyte and ignores the specific interactions between ions (including sodium and potassium) and charged interface. These interactions, as described by the Freundlich and Langmuir isotherms<sup>9,10</sup>, must be as fundamental to the structure and function of biological colloids as they are to mineral colloids<sup>11</sup>. The fixed-charge theory<sup>12</sup> had not been applied to the oil membrane; interestingly, however, the Donnan term was

\* Present address: Department of Biochemistry, Albert Einstein College of Medicine, New York 61, New York.

shown to be identical with the Gouy potential<sup>11</sup> and obviously could not account for specific interactions (ref. 8, p. 176).

With cogent arguments, which were neither rebuffed to satisfaction<sup>12</sup> nor explored further, Ehrensvard and Sillen<sup>13</sup> provided momentum and clarity to the Beutner-Baur controversy. They<sup>13</sup> pointed out the inconsistencies and inadequacy of the distribution and Henderson potentials and proposed an equation containing the Langmuir isotherm in two terms, one of which is a modified Gouy potential. The new equation, vindicating Baur, brings forth the concept of the adsorption; however, neither theory nor experiment with this<sup>13,14</sup> and the other equations explained the role of the fixed head charges in the origin of the potential. The practical  $\Delta V$ -log  $c$  plot of all these equations has the form of the Nernst, concentration, diffusion, distribution and Henderson potentials, all of which look alike, put the emphasis on the electrolyte and tend to make one lose sight of the charged components of the membrane. In the present article I shift the emphasis from the mobile ions to the charged interface, and develop the concept that the membrane potentials are caused by the appearance and disappearance of the fixed head charges of the amphipathic molecules of phospholipids and other surfactants orientated at the oil/water interface.

The experiments were performed at 25° C in a modification of the 'hanging drop' cell described by Dean<sup>15</sup> and similar to the cells used by Beutner<sup>3</sup> and Baur<sup>4</sup>. A layer of water-saturated pentanol separated two electrolyte solutions at the lower (A) and upper (B) interfaces (Fig. 1). Two saturated calomel electrodes connected the lower and upper electrolytes respectively to the positive and negative poles of a high impedance electrometer, Keithley model 610A. The electrolyte solutions were prepared by dissolving the salts in pentanol-saturated water, which was glass-distilled and had a specific resistance of a megohm cm before shaking with the alcohol. Diameter of the circular interface was 2.5 cm.

Fig. 1. Relation of sign of  $\Delta V$  to sign of head charge of surfactant

The change of potential at a given interface was studied by injecting given quantities of surfactant at that interface without disturbing the other interface. It is expected<sup>4</sup> that the amphipathic molecules at the interface orientate themselves with the head charges in the water and the non-polar chains in the oil. The potential was measured immediately before and after the injection, and the difference  $\Delta V$  was calculated. A sudden change of potential ensued on injection, and the new potential decayed at a rate depending largely on the surfactant's solubility and disappearance from the interface.

In brief (Fig. 1), a negative head charge at the lower interface A or a positive head charge at the upper interface B produced a positive change of potential (+a, +d); conversely, a positive head charge at the lower interface A or a negative head charge at the upper interface B produced a negative change of potential (-b, -c). Conclusively, the sign of the potential was determined by the sign of the fixed head charges of the amphipathic molecules<sup>4</sup> as they appeared at the oil/water interface. Baur<sup>4</sup> claimed that the sign of the charged interface determines the sign of

the potential; but no evidence was given for it before these experiments.

The size of the potential changes varied with the concentration of the electrolyte<sup>4</sup> in line with the Gouy equation<sup>11</sup> and with the equation and data of Ehrensvard and Sillen<sup>13,14</sup>. Typically (Table 1), the change of potential was smallest in 1 M potassium chloride and increased with decreasing electrolyte concentration. As expected, the absence of electrolyte causes expansion of the double layer, which then shows a conspicuous head charge and a large potential; conversely, a large salt concentration compresses the double layer with consequent masking of the head charges and decrease of the potential. Similarly, the presence of polyvalent ions (calcium, magnesium, sulphate) in the water phase caused changes of potential consistent with the adsorption of the counter-ions and masking of the head charges.

Table 1. EFFECT OF ELECTROLYTE CONCENTRATION ON THE OIL/WATER POTENTIALS OF TYPICAL ANIONIC (SODIUM DEOYL SULPHATE, SDS) AND CATIONIC (OCTYLTRIMETHYLAMONIUM BROMIDE, CTAB) SURFACTANTS

Surfactant Electrolyte (M)	Potentials in mV $\pm 2$				
	SDS KCl	SDS CaCl <sub>2</sub>	CTAB KCl	CTAB K <sub>2</sub> SO <sub>4</sub>	Cephalin CaCl <sub>2</sub>
1.0	39	22	-40	—	0
0.1	65	48	-62	-8	3
0.01	110	70	-84	-18	63
0.001	140	109	-150	-80	105
Water	158	—	-220	—	180

A solution of 0.001 M KCl was kept at interface B, while 1 mmole SDS or CTAB in 0.1 ml. water or animal cephalin in 0.3 ml. pentanol was applied with a micropipette at interface A on the electrolyte solutions of the given concentration. Membrane thickness: 10 mm.

As predicted by Fig. 1, the largest potentials were obtained when charges of opposite sign lined the opposing interfaces (+a +d; and -b -c), where no difference in electrolyte concentration was required. These potentials, obviously, increased with decreasing electrolyte concentrations and became largest on water. On injection of SDS and CTAB on water at A and B respectively,  $\Delta V$  reached the value of 370 mV. Wilbrandt<sup>16</sup> obtained these large 'asymmetry' potentials with collodion membranes and used them as the strongest argument against the assumption that they were diffusion potentials.

By comparison with the anionic SDS and the cationic CTAB (Table 1), a preparation of animal cephalin<sup>4</sup> as well as certain preparations of synthetic phosphatidylethanolamine and phosphatidylcholine (Nutritional Biochemical Corp.) behaved like anionic surfactants. Thin-layer chromatography of these preparations showed the presence of large quantities of acidic components, which would account for the appreciable size of the anionic-type potential on water; under the same conditions, chromatographically homogeneous egg lecithin produced a zero change of potential.

In similar experiments (Table 2), a solution of surfactant in pentanol separated a solution of 1 M potassium chloride at interface B and solutions of variable electrolyte concentration at interface A.

Table 2. EFFECT OF ELECTROLYTE CONCENTRATION ON THE ELECTROCAL POTENTIAL OF ANIONIC AND CATIONIC OIL MEMBRANES

At A KCl (M)	Potential in mV $\pm 2$			
	SDS	OTAB	Myristoylcholine chloride	Acetylcholine bromide
0.1	40	-48	-51	-15
0.01	92	-98	-98	-30
0.001	125	-142	-144	-49

The anionic membrane of sodium decyl sulphate reflects the combination of events +a and -b of Fig. 1. The positive  $\Delta V$  is the sum of a large positive potential of the anionic head charge in dilute potassium chloride at interface A and a much smaller negative potential of the same head charge in concentrated potassium chloride at interface B. Conversely, the negative  $\Delta V$  of the cationic membranes of CTAB, myristoylcholine chloride and acetylcholine bromide is the combination of a large negative potential (-c) of a cationic surfactant in dilute potassium chloride at A and a smaller positive (+d)

potential of the same cationic in concentrated potassium chloride at B. As expected, the shorter the chain of the amphipathic molecule (acetylcholine versus CTAB) the smaller the potential, or the longer the chain the more stable the interfacial film. Accordingly, injection of acetylcholine bromide on 0.01 M potassium chloride at interface A caused a potential change of -15 mV, which vanished in 2-3 sec; whereas CTAB produced -82 mV, which decayed only 5 mV in the first minute.

The potentials in Tables 1 and 2 were independent of the type of electrode pair used: that is, saturated calomel, Ag/AgCl in 4 M potassium chloride, copper or platinum in 4 M potassium chloride. These electrodes are not suitable to measure concentration potentials of either the small (potassium chloride) electrolyte or the surfactant in bulk; and, experimentally, the electrodes had no contact with the surfactant. With that in mind, the observed oil/water potentials cannot possibly be concentration or distribution potentials, both of which are electrode potentials, are irrelevant and (Baur<sup>4</sup>) "do not exist" as membrane potentials.

The electrical model of the oil membrane is not yet available. The foregoing data, however, indicate that this type of membrane has two properties (sign and electrolyte dependency of the potential) which distinguish it sharply from the ordinary ion exchange membrane. When I used cationic and anionic 'Amphion C-60 and A-60' (American Machinery and Foundry Company) solid membranes in place of the oil membrane in Fig. 1, the resulting potentials had signs opposite to those in Tables 1 and 2 and increased with increasing electrolyte (potassium chloride) concentrations. Similarly, the electrical potential of the anionic clay membrane<sup>17</sup> as calculated from the fixed charge theory<sup>11</sup> and as measured in the laboratory<sup>17</sup>

increased with the electrolyte concentration, whereas the potential of the oil membrane decreased with increasing concentration of potassium chloride. Henceforth, the electrolyte does not play a direct part in the origin of the potential of the oil membrane except for masking and unmasking the head charges at the interface. Polyvalent ions (calcium, magnesium, sulphate) and all kinds of long-chain ions, which are known to be preferably adsorbed on charged colloids, were particularly effective in depressing the oil/water potentials, which in that respect resemble the electrokinetic or zeta potentials<sup>8</sup>. Once the interfacial charge is destroyed the membrane potential vanishes; and that is true also for ordinary ion exchange membranes. The cited differences and similarities between the two types of membranes and biological membranes remain to be investigated.

## NEW PYRETHRIN-LIKE ESTERS WITH HIGH INSECTICIDAL ACTIVITY

By DR. M. ELLIOTT, DR. N. F. JANES, K. A. JEFFS, P. H. NEEDHAM, and DR. R. M. SAWICKI

Department of Insecticides and Fungicides, Rothamsted Experimental Station, Harpenden, Hertfordshire

NEW esters of chrysanthemic acid have been prepared with highly specific insecticidal action. Two of the new compounds are more toxic to some insect species than the natural pyrethrins or allethrin, and are more stable than the natural pyrethrins.

Several non-ketonic esters of chrysanthemic acid (I), such as dimethrin (from 2,4-dimethylbenzyl alcohol, IIa) and barthrin (from 6-chloropiperonyl alcohol), have useful insecticidal activity<sup>1</sup> but are less toxic to many insect species than are esters from pyrethrolone (IIIa), cinerolone (IIIb), and allethrolone (IIIc). In 2,4-dimethylbenzyl alcohol (IIa), the 4-methyl group is held by the benzene ring in a steric relation to the H—O bond of the alcohol similar to that between the side-chain CH<sub>2</sub>X and the HO link in the cyclopentenolones (III). Unsaturated side-chains CH<sub>2</sub>X in the chrysanthemates of the ketols (III) are important for insecticidal activity<sup>2,3</sup>, so 4-alkenylbenzyl chrysanthemates were examined for their activity.

To adult female *Musca domestica* L. (house-flies), treated topically with measured drops of solutions in acetone<sup>4</sup>, 4-allylbenzyl (+)-*trans*-chrysanthemate (from IIb) was approximately four times, and the (±)-*ois-trans*-chrysanthemate twice, as toxic as the mixture of esters of the natural pyrethrins. By this method the mixed pyrethrins, allethrin (from IIIe), and pure pyrethrin I (ref. 5) were equitoxic and 4-allylbenzyl (±)-*ois-trans*-chrysanthemate (ABC) was seven times more toxic than

dimethrin. ((±)-*Ois-trans* esters were prepared from the commercially available ethyl ester, which contained approximately 30 per cent *ois*-isomers; (+)-*trans*-chrysanthemic acid was naturally derived.) But to adult *Phaedon cochleariae* Fab (mustard beetles), treated similarly, allethrin was twice as toxic as dimethrin and six times more toxic than ABC. (Relative toxicities are expressed as inverse ratios of median lethal doses, LD<sub>50</sub>.) Methyl groups on the benzene ring of ABC increased toxicity to mustard beetles considerably. Thus, 4-allyl-2,6-dimethylbenzyl (±)-*ois-trans*-chrysanthemate (DMABO) (from IIc) was twice as toxic as allethrin and half as toxic as the natural pyrethrins mixture to mustard beetles and just significantly more toxic than ABC to house-flies. (New compounds are protected by British Patent applications 10701/63, 10702/63 and 42715/63, and corresponding foreign applications assigned to the National Research Development Corporation.) 4-Allyl-2,6-dimethylbenzyl and 4-allylbenzyl (+)-*trans*-chrysanthemates were more toxic to house-flies than was any other pyrethrin-like ester, natural or synthetic; also with other insect species (for example, *Tribolium castaneum* (Herbst.), *Periplaneta americana* (L.), *Aphis fabae*, Scop., and the red spider mite *Tetranychus telarius* (L.)), both in laboratory tests and conditions nearer to practical use, the 2,6-dimethyl compound (DMABO) was as toxic or more so than allethrin. The insecticidal activity of a film of DMABO, irradiated with ultra-violet light, persisted longer than that of

(I)

(III)

comparable deposits of allethrin or the natural pyrethrins.

The relationship between toxicity to house-flies and mustard beetles and chemical structure in esters related to the allyl compounds already mentioned was examined in detail. To both species, 4-allylbenzyl esters were more toxic than 4-*n*-propyl compounds; similarly, allethrin was more active than its *n*-propyl analogue<sup>4</sup>. 4-Allylbenzyl esters were about ten times more active than 3-allyl compounds and 2-allylbenzyl esters gave no kill at the largest doses. This showed that it was important to maintain the appropriate steric relation between the unsaturated side-chain of the alcohol and the linkage to the acid portion of the molecule. Esters in which the side-chain double bond was conjugated with the benzene ring (from 4-vinyl and 4-propenylbenzyl alcohols, II*d* and II*e*, respectively) did not kill mustard beetles and were only slightly toxic to house-flies. The ester from the enyne alcohol (IV) (ref. 6) in which an acetylenic link maintained a steric relation between the hydroxyl and allyl groups similar to that in 4-allylbenzyl alcohol was not toxic either to mustard beetles or house-flies, so this steric relation on its own was insufficient to give insecticidal activity.

(IV)

(V)

Most of the alcohols formed more toxic chrysanthemates when the hydrogen atoms *ortho* to the CH<sub>2</sub>OH group (II, R<sup>1</sup> and R<sup>2</sup>) were replaced with methyl groups. The 4-allyl-2,6-dimethyl ester was the most toxic compound to mustard beetles, but to both species the ester from 4-allyltetramethylbenzyl alcohol (II*f*) was less toxic than the 2,6-dimethyl compound. The 4-*trans*-crotylbenzyl alcohol (II*g*) gave esters less toxic to both species than esters of 4-allylbenzyl alcohol (II*b*) but, to mustard beetles only, the ester from 4-(2'-methallyl) benzyl alcohol (II*h*) was better than that from 4-allylbenzyl alcohol.

The ester from the readily accessible 4-*trans*-sorbitylbenzyl alcohol (II*i*) was only one-twentieth as toxic as the 4-allyl compound to house-flies and one-tenth as toxic to mustard beetles.

2-, 3- or 4-Allyloxybenzyl chrysanthemates had little insecticidal activity, less than that of the corresponding methoxy compounds. Free hydroxyl groups suppressed toxicity; the ester from the alcohol (V), easily made from *O*-allyl kojic acid<sup>7</sup>, was not insecticidal. Methoxyl groups at any position on the ring decreased the toxicity of otherwise active compounds. Thus, Barthel *et al.*<sup>8</sup> made 3-allyl-4-methoxy- and 4-ethoxybenzyl chrysanthemates, and we made 3-allyl-4-methoxy- and 4-allyl-3-methoxybenzyl chrysanthemates; but all were much less effective than the related unmethoxylated allyl benzyl esters.

The high toxicity of the 4-alkenylbenzyl chrysanthemates led to an investigation of methylbenzyl compounds. The 2,4-, 3,4- and 2,6-dimethyl esters had already been tested<sup>1</sup>. 2,4,6-Trimethylbenzyl (±)-*cis-trans*-chrysanthemate (from II*j*) was approximately one-third as toxic as DMABO to house-flies and about twice as toxic as dimethrin to house-flies and mustard beetles. Penta-methylbenzyl (±)-*cis-trans*-chrysanthemate (from II*k*) was significantly more toxic than the 2,4,6-trimethyl ester to mustard beetles, but less active to house-flies. 2,4,6-Triethyl benzyl alcohol (II*l*) gave a non-toxic ester. Other dimethyl esters were less toxic than the 2,4- and 3,4-dimethyl compounds. 2,4- and 3,4-Dichlorobenzyl chrysanthemates were less toxic than the corresponding dimethyl compounds.

Thus, those benzyl alcohols the structures of which relate them most closely to pyrethrolone, cinerolone, etc. (III), give the most toxic chrysanthemates. 4-Allylphenyl and 4-allyl-2,6-dimethylphenyl chrysanthemates, which have some structural features in common with the benzyl esters but differ stereochemically, had no insecticidal activity; this indicated that there must be a specific and appropriate stereochemical relationship between the acidic and alcoholic parts of the esters. The 4-allyl-2,6-dimethylanilide of (±)-*cis-trans*-chrysanthemic acid differs little from DMABO stereochemically but obviously lacks the requisite chemical properties, for it was not toxic.

Molecular models show that, when the allyl groups in allethrin and in 4-allyl-2,6-dimethylbenzyl chrysanthemates are orientated similarly relative to the chrysanthemic acid parts of the molecules, one of the 2,6-dimethyl groups in the benzyl ester occupies a position equivalent to that of the methyl group on the cyclopentenolone ring; a possible explanation for the lack of toxicity of 2,4,6-triethylbenzyl chrysanthemate is that here there is no room for an ethyl group to be similarly accommodated. Additional evidence that the high insecticidal activity of the 4-allyl and 4-allyl-2,6-dimethylbenzyl esters is associated with their similarity in molecular shape to the natural esters and allethrin is that (+)-*trans*-chrysanthemic acid gives esters approximately twice as toxic to house-flies as those from the (±)-*cis-trans*-acid, and that, to house-flies and mustard beetles, the 2,4,6-trimethylbenzyl ester of (+)-*trans*-chrysanthemic acid is much more active than that from (-)-*trans*-chrysanthemic acid. Analogous results were obtained with cyclopentenolone esters of (+), (-), and (±)-*cis-trans* acids<sup>9,10</sup>. The results support an earlier suggestion<sup>8</sup> that the insecticidal activity of the pyrethrins and related compounds depends partly on the cyclopentenolone ring acting as a planar activating nucleus to hold the unsaturated side-chain in an appropriate stereochemical relationship to the alcoholic link and thence to the acid. In these benzyl esters the benzene ring fulfils this role.

Neither ABC nor DMABO was well synergized by piperonyl butoxide in activity against house-flies.

Details of the synthesis of the new compounds and of the biological data will be published.

This work formed part of a project supported by the National Research Development Corporation. We thank

Mr. F. P. W. Winteringham for a helpful discussion at an early stage in this work and Dr. C. Potter for his help and advice.

## STEREOSPECIFICITY OF CERTAIN SOLUBLE AND PARTICULATE PREPARATIONS OF MITOCHONDRIAL REDUCED NICOTINAMIDE-ADENINE DINUCLEOTIDE DEHYDROGENASE FROM BEEF HEART

By DR. LARS ERNSTER\*, PROF. HENRY D. HOBERMAN†, ROBERT L. HOWARD‡, PROF. TSOO E. KING‡, DR. CHUAN-PU LEE§, DR. BRUCE MACKLER||, and DR. GIANLUIGI SOTTOCASA¶

Wenner-Gren Institute, University of Stockholm, Sweden

IN recent years several preparations of soluble and particulate NADH dehydrogenase have been described, and the question, whether any or all of these are derivatives of the mitochondrial, respiratory chain-linked NADH dehydrogenase, has been the subject of intense investigations and discussions<sup>1</sup>. Recently, it has been established that the respiratory chain-linked NADH dehydrogenase reaction involves the 4B hydrogen atom of NADH, as revealed by studies with submitochondrial particles from beef heart<sup>2,3</sup> and rat liver<sup>4</sup>. Simultaneously it was found that a number of other NADH-oxidizing enzymes, including pyridine nucleotide transhydrogenase<sup>5,6</sup>, DT diaphorase<sup>7</sup>, the microsomal NADH-cytochrome c reductase<sup>8,9</sup>, as well as a liver-mitochondrial NADH-cytochrome c reductase catalysing the oxidation of extramitochondrial NADH<sup>10</sup>, are 4A-specific with regard to NADH. From these results it appeared that determination of the stereospecificity with regard to NADH might be a useful tool in characterizing various purified preparations of NADH dehydrogenase. This article presents results regarding the stereospecificity of samples of soluble NADH dehydrogenase prepared from beef heart according to various current procedures. Results are also presented regarding the stereospecificity of NADH oxidation as catalysed by the Keilin-Hartree heart-muscle preparation<sup>7</sup>, as well as a purified preparation of Straub's diaphorase<sup>6</sup> ( $\alpha$ -lipoyl dehydrogenase<sup>11</sup>). As will be shown, the NADH dehydrogenase reaction catalysed by all these preparations involves the 4B hydrogen atom of NADH.

NADH dehydrogenase of King and Howard<sup>12</sup> was prepared as described by these authors<sup>13</sup>, except that fractions were isolated using narrower cuts. The preparation was free of FAD. Singer's<sup>14</sup> NADH dehydrogenase was prepared according to the improved procedure described by Cremona and Kearney<sup>15</sup>. The purification was pursued until the step before the centrifugation on a sucrose gradient. Mackler's<sup>16</sup> procedure for preparing NADH dehydrogenase was followed precisely as described.  $\alpha$ -Lipoyl dehydrogenase was purified essentially as described by Massey<sup>17</sup>. The preparation contained no FMN. Heart-muscle preparation was made by Keilin and

Hartree's<sup>7</sup> method as adapted by King<sup>18</sup>. The preparation was slightly deficient in cytochrome c. NADH-4A-<sup>3</sup>H and NADH-4B-<sup>3</sup>H were prepared from NAD<sup>+</sup>-4-<sup>3</sup>H by reduction with unlabelled UDPG+UDPG dehydrogenase and with unlabelled ethanol + alcohol dehydrogenase, respectively, as previously described<sup>19</sup>. NAD<sup>+</sup>-4-<sup>3</sup>H (specific activity 0.7 mo./mmole) was prepared by the method of Krakow *et al.*<sup>19</sup>.

All enzyme preparations were assayed in the presence of NADH-4A-<sup>3</sup>H or -4B-<sup>3</sup>H, under two sets of conditions: (1) with an excess of ferricyanide as the electron acceptor; (2) in the absence of electron acceptor. In the former case, the reaction was followed by measuring the reduction of ferricyanide at 420 m $\mu$  in a Beckman DK-2 recording spectrophotometer; the exact conditions and the reaction rates measured are stated in Table 1. When virtually all NADH was oxidized (after about 2-3 min), the samples were frozen in a dry ice-acetone mixture, and water was isolated by sublimation as previously described<sup>20</sup>. A portion of the isolated water was used for counting radioactivity with a Packard model 314 HX 'Tri-Carb' liquid scintillation counter. In the absence of added electron acceptor the incubation mixture was the same as when acceptor was present except that larger amounts of enzyme were used (compare Table 2) and the time of incubation was 5 min. The Keilin-Hartree heart-muscle preparation was also assayed with respect to NADH oxidase activity by following the aerobic oxidation of NADH at 340 m $\mu$ . Again the reaction was followed until virtually all NADH was oxidized. The tritium in water was determined as already described here.

The results are summarized in Tables 1 and 2. Both in the presence (Table 1) and in the absence (Table 2) of a terminal electron acceptor, there occurred a substantial

The incubation mixtures were similar to those in Table 1, except that no electron acceptor was added, and the amounts of enzyme (mg protein) were as follows: (1) 0.37; (2a) 0.14; (2b) 0.22; (2c) 0.18; (3) 0.064. The samples were incubated at 30° C for 5 min.

detrition of NADH-4B-<sup>3</sup>H, and essentially no detrition of NADH-4A-<sup>3</sup>H, with all the enzyme preparations tested. Thus, all preparations contained almost exclusively 4B-specific NADH dehydrogenase, and catalysed also an exchange of hydrogen atoms between NADH and water. The NADH oxidase activity of the Keilm-Hartree preparation was likewise 4B-specific (Table 1), as expected on the basis of earlier results<sup>1</sup>. The finding that the detrition was not complete in the samples containing ferricyanide (Table 1), in spite of virtually complete oxidation of NADH (as assessed spectrophotometrically), is apparently due to an isotope effect, indicating that the actual transfer of hydrogen from NADH to the enzymes was rate-limiting. Complete detrition occurred, in fact, in the NADH oxidase reaction of the Keilm-Hartree preparation, the rate of which was much lower than that of the corresponding ferricyanide reduction, that is, the rate-limiting step apparently was on the acceptor side of the NADH dehydrogenase. Rotenone, which blocked the NADH oxidase reaction of the Keilm-Hartree preparation but not the reduction of ferricyanide with any of the preparations tested, had no effect on the rate of detrition. This finding, in accord with previous results<sup>2,3</sup>, indicates that rotenone does not block the transfer of hydrogen from NADH to NADH dehydrogenase with any of the preparations studied.

Table 3 is a summary of previous and present conclusions regarding the stereochemical properties of various enzymes catalysing the oxidation of reduced pyridine nucleotides. The respiratory chain-linked NADH dehydrogenase and the α-lipoil dehydrogenase are specific for the 4B hydrogen atom of NADH. The soluble NADH

DT diaphorase	A	A	2

dehydrogenase of King and Howard<sup>10</sup>, Singer<sup>13</sup>, and Mackler<sup>14</sup> are 4B-specific. Since these preparations were free of FAD and/or of α-lipoil dehydrogenase activity, they most probably represent derivatives of the NADH dehydrogenase of the respiratory chain. A similar conclusion may hold for Mahler's<sup>17</sup> enzyme, the stereo-specificity of which has been determined by Drysdale and Cohn<sup>18</sup>. In contrast to these enzymes are the microsomal NADH-cytochrome c<sup>4</sup> or -cytochrome b<sub>5</sub> reductase<sup>8</sup>, the 'external' NADH-cytochrome c reductase of liver mitochondria<sup>9</sup>, DT diaphorase<sup>2</sup>, and the pyridine nucleotide transhydrogenase<sup>2,3,5</sup>, which are specific for the 4A hydrogen atom of NADH; interestingly, the transhydrogenase is 4B-specific with regard to NADPH, whereas DT diaphorase is 4A-specific. Another interesting feature is that the two 4B-specific NADH-oxidizing enzymes, NADH dehydrogenase and α-lipoil dehydrogenase, catalyse a ready exchange of hydrogen atoms between NADH and water, whereas the 4A-specific NADH-oxidizing enzymes seem to be devoid of this capacity. These and further aspects of the stereochemistry of enzymes catalysing the oxidation of reduced pyridine nucleotides may be of value for the study of their reaction mechanism and metabolic function.

## AMINO-ACIDS AND PEPTIDES IN HUMAN GASTRIC JUICE WITH PARTICULAR REFERENCE TO PERNICIOUS ANAEMIA: A REVIEW

By DR J. G. HEATHCOTE and R. J. WASHINGTON  
Royal College of Advanced Technology, Salford

NUMEROUS investigations have been carried out, in the past, on the gastric juice of both normal subjects and pernicious anaemia patients. In the main, these researches have been concerned with the protein fraction of gastric juice, often in an endeavour to isolate the 'intrinsic factor' first proposed by Castle<sup>1</sup>. This factor, which has never been isolated, has been assumed to be protein in nature since the work of Ternberg and Eakin<sup>2</sup> and of Glass *et al.*<sup>3</sup>. Much of this research has been well described in reviews<sup>4-10</sup>, and a good deal of knowledge of

the proteins of gastric juice has accrued from the search for this elusive factor. Less information seems to be available concerning the non-protein nitrogenous fraction of human gastric juice, and the present review is an attempt to summarize our existing knowledge of this fraction.

The earlier investigations<sup>11,12</sup> on protein-free gastric juice were inconclusive and it was not until 1931 that Martin<sup>13</sup> carried out the first meaningful examination. He precipitated the protein by means of sodium tungstate and,

after filtration, analysed the filtrates for nitrogen by the method of Folin and Wu<sup>14</sup>. The non-protein nitrogen in normal samples was found to vary over the range of 20–48 mg/100 ml. gastric juice. In simple achlorhydria, the range was 30–90 mg per cent, while in pernicious anaemia, it was 60–150 mg per cent. Martin also observed that the volume of gastric juice produced by the fasting pernicious anaemia patient was very small when compared with that produced by a fasting normal subject.

In a further investigation<sup>15</sup>, carried out two years later, Martin showed that both the amino-acid-nitrogen and the non-protein-nitrogen were twice as great as the normal values in cases of benign achlorhydria and three times as great in pernicious anaemia. Martin's investigations were carried out before the advent of paper chromatography, and he obtained no details of the individual amino-acids which were present. In the next section, we shall examine results which have been obtained in more recent studies on normal gastric juice.

**Amino-acids in Normal Gastric Juice.** Cagianut, Zehnder and Nager<sup>16</sup> precipitated the proteins from normal gastric juice by the addition of excess alcohol and examined the protein-free solution, after centrifugation, by means of paper chromatography. They found small quantities of alanine, leucine, histamine and glucosamine.

Two years later, Gilligan, Moor and Warren<sup>17</sup> compared the results obtained by alcoholic precipitation and dialysis. On examination of the protein-free solutions these authors found alanine, aspartic acid, glycine, valine and the leucines (not separated) to be present in all cases. In addition  $\gamma$ -amino-butyric acid, glutamic acid, glutamine and tyrosine were often present; other amino-acids occurred on rare occasions. The dialysates and alcoholic filtrates proved to be almost identical in amino-acid composition, and the leucines, valine and alanine accounted for two-thirds of the total concentration of the free amino-acids. The individual amino-acids were estimated by visual comparison of the colour produced by ninhydrin with that produced by standard amounts of each acid.

Merlevede, Pottiez and Verhelle<sup>18</sup>, in 1955, precipitated the proteins of gastric juice with trichloroacetic acid (20 per cent), removed them by filtration, and then demineralized the filtrate by passing it through a column of resin ('Amberlite IR-120'). The amino-acids were eluted by means of ammonia, and the eluate was concentrated *in vacuo* at room temperature. The samples were chromatographed as bands, and each band was then resolved into its component amino-acids by paper electrophoresis. In the gastric juice from ten normal subjects, lysine, histidine, leucine, phenylalanine, glycine, alanine, serine, tyrosine, glutamic acid, glutamine, valine and citrulline were found in every case. In a few samples ornithine, threonine, aspartic acid, proline and methionine were also found. The reported presence of ornithine and citrulline was rather surprising.

Chiba and Ishikawa<sup>19</sup> deproteinized their samples of normal gastric juice by heating to 80° with perchloric acid (8.6 per cent) and then filtering. Paper chromatography showed the presence of aspartic acid, cystine, alanine, histidine, valine and/or methionine, leucine and/or isoleucine. Some of these amino-acids may possibly have been produced by partial hydrolysis of peptide links during the preparation of the protein-free filtrate using hot perchloric acid.

Shimizu<sup>20</sup> examined seven samples of gastric juice from patients with non-gastric disease. He deproteinized the juice by alcoholic precipitation and then examined the filtrates by chromatography. Valine, leucine, alanine, serine and tyrosine were present in all cases. This was in agreement with the results obtained by Merlevede *et al.* already mentioned.

After removal of the protein in their samples by dialysis, Bouda and Veselý<sup>21</sup> used paper electrophoresis and paper chromatography to separate the amino-acids in the filtrates. In six samples of normal fasting juice which they

examined, histidine, arginine, serine, tyrosine, phenylalanine, aspartic acid and glutamic acid were found. Bouda and Veselý<sup>21</sup> reported that Hais and Macek<sup>22</sup> found the same amino-acids as Gilligan *et al.*<sup>17</sup>, and in addition they found serine and threonine to be present.

The technique of adsorption on to a column of 'Dowex-50' resin was used by Borkowski<sup>23</sup> to examine a series of filtrates of normal fasting gastric juice, after the protein had been removed by means of alcohol. The amino-acids were then eluted with dilute ammonia and identified by paper chromatography in the usual way. Borkowski found altogether some 17 amino-acids of which ten were always present. These were leucine, valine, glycine, alanine, glutamic acid, serine, lysine, threonine, aspartic acid and tyrosine. A quantitative estimation was possible for eight of these (Table 1). He found no histidine or citrulline, in contrast to Merlevede *et al.*<sup>18</sup>, but claimed the additional presence of glutamine, arginine,  $\beta$ -amino-isobutyric acid, phenylalanine, proline, ornithine and hydroxyproline in this decreasing order of occurrence.

Table 1. THE CONCENTRATION OF AMINO-ACIDS IN NORMAL GASTRIC JUICE (BORKOWSKI, 1960)

Amino-acid	Concentration (mg/100 ml.)
Aspartic acid	0.64
Glycine	0.53
Glutamic acid	0.47
Lysine	0.46
Tyrosine	0.35
Alanine	0.34
Threonine	0.27
Serine	0.26

Fucik and Bolková<sup>24</sup> investigated normal gastric juice for amino-acids and peptides. The juice was first treated with a mixture of alcohol and acetone, and the protein-free filtrate was examined by paper chromatography and electrophoresis.

They found, in addition to the amino-acids reported by Borkowski, methionine, valine, phenylalanine, leucine, isoleucine, histidine, arginine and  $\gamma$ -aminobutyric acid to be present in nearly all the subjects examined.

**Comparative Investigations of Normal and Pernicious Anaemia Juice.** Hiller and Bischof<sup>25</sup>, in 1953, compared the free amino-acids in the dialysates of the gastric juice of five normal subjects and several patients suffering from diseases of the stomach. Two of the patients with gastritis had atrophy of the gastric mucosa which may well have been incipient pernicious anaemia. The samples of dialysate were concentrated over phosphorus pentoxide and then examined by paper chromatography.

Qualitatively, they found little difference between the amino-acids of normal gastric juice and those of the patients. In all cases they found serine phosphoric acid, aspartic acid, serine, glutamic acid, glycine, lysine, threonine, alanine, arginine, valine, and leucine. There was an estimated increase in the concentration of amino-acids in the two cases of gastric atrophy; but, unfortunately, it was not possible to determine quantitatively the small amount of amino-acids present in normal juice. The values which these authors quoted for the concentrations of the amino-acids in the cases of gastric atrophy were about one-fiftieth of the concentrations reported by Washington<sup>26</sup> for the amino-acids present in pernicious anaemia (see following).

In a comparative investigation of the protein-free filtrates of normal gastric juice and those from pernicious anaemia patients, Norpoth, Surmann, and Clöges<sup>27</sup> used alcohol for the precipitation of the protein. They found, using paper chromatography, that valine, leucine, alanine, glutamic acid, aspartic acid and phenylalanine were frequently present, while histamine, tryptophan, lysine, threonine and  $\gamma$ -amino-butyric acid were less frequent. The gastric juice of pernicious anaemia (and of gastric cancer) contained greater numbers of amino-acids than normal gastric juice. The amino-acids were also present in increased concentration.

In 1960, Bouda and Veselý<sup>21</sup>, using the same techniques as before<sup>21</sup>, carried out a direct comparison between the

gastric juice of normal subjects and of patients suffering from gastric atrophy. In normal juice, they found most of the amino-acids reported by Norpoth *et al.* and in addition methionine, tyrosine, serine, glycine and arginine. In diseases associated with gastric atrophy, such as cancer and pernicious anaemia, both the number and concentration of free amino-acids were increased.

Washington<sup>17</sup> has recently examined the non-protein fraction of two samples of pooled normal human gastric juice and compared his results with those obtained from a few (individual) samples of juice from pernicious anaemia patients. All samples were of fasting juice and, except in the case of one sample of pernicious anaemia, were taken without any artificial stimulation such as histamine or alcohol. Washington deproteinized the gastric juice from normal subjects by three different methods, namely, dialysis, precipitation with trichloroacetic acid, and precipitation with ethanol. On paper chromatography and staining with ninhydrin the protein-free filtrates, however prepared, produced a prolonged streak which was interspersed with regions of increased intensity. The streaking was eventually shown to be due to the presence of a peptide which was causing the individual amino-acids to bond together and to be transported, in part, to atypical positions along the line of the chromatogram. The regions of increased intensity represented the true main positions of the amino-acids. The problem of separation of the individual components was resolved by developing a band of the filtrate in one solvent and eluting the main component bands thus produced. The elution was carried out with water and, after concentration, the eluates were chromatographed again as individual bands in a second solvent system. The new bands (sub-fractions) from these second chromatograms were eluted and concentrated as before, and chromatographed again a third time, either in the first solvent or in a different one. At this third stage discrete bands were obtained, on staining. The bands which corresponded to the same individual amino-acids in each sub-fraction were treated together for colorimetric determination.

The gastric juice from patients with pernicious anaemia proved to be more easily analysed owing to the absence of peptide and, in this case, it was possible to carry out two-dimensional chromatography directly on the eluates of the bands derived from the first chromatographic separation.

The main findings are summarized briefly in Table 2, from which it can be seen that the sample of pernicious anaemia gastric juice has an overall concentration of amino-acids which was almost five times as great as that of the average sample of normal gastric juice. Individual samples of juice, of either kind, contained other amino-acids such as methionine or phenylalanine, but Washington found no trace of ornithine or of citrulline.

Alcohol-stimulation of the production of gastric juice in one pernicious anaemia patient was found to increase the concentration of the amino-acids in the non-protein filtrate above the value obtained without such stimulation.

Only a few samples were examined by Washington, but the quantitative recovery of the amounts of amino-acids which are present, in non-stimulated normal gastric juice, was good. Furthermore, the values which he obtained, for the overall concentration, were within the ranges quoted by earlier workers in the field (Table 3). There is every reason to believe that the results which were obtained in the pernicious anaemia juice were, if anything, even more reliable, owing to the larger concentrations of amino-acids present and the relative simplicity of the analysis.

**Peptides in Gastric Juice.** On hydrolysis of the non-protein filtrates of normal gastric juice, Gilligan *et al.*<sup>18</sup> observed that the concentration of the amino-acids increased ten-fold and this seemed to indicate that many of the amino-acids were present combined in peptide chains. In their examination of the alcoholic filtrates and dialysates of normal juice, they claimed that a peptide was often present which migrated faster than leucine in chromato-

Table 2. FREE AMINO-ACIDS IN FASTING GASTRIC JUICE (WASHINGTON, 1964)

\* Obtained from the figure quoted for the amino-acids by assuming a value of 120 for the average mol. wt.

graphic solvents, and which they called the 'high streak' peptide.

Norpoth, Surmann and Clöages<sup>19</sup> also reported the incidence of a similar 'high streak' peptide.

Bouda and Vesely<sup>20</sup>, in 1960, described the presence of "peptide streaks" in some experiments with normal gastric juice, but these were not investigated further. These workers also found that the juice of patients suffering from gastric atrophy (either pernicious anaemia or cancer) rarely contained peptides.

In 1960 also, Brummer and Kulonen<sup>21</sup>, after precipitation of the proteins of gastric juice, found a spot to be present on paper chromatograms of all alcoholic filtrates where the pH of the gastric juice was below 3.0. This spot, which they called spot "A", migrated faster than leucine, but could not be characterized adequately. In the next year, Brummer, Seppala and Kulonen<sup>22</sup>, by means of column chromatography, separated spot "A" from other components and then examined it by means of paper chromatography. They found "A" to consist of two components—a weakly-staining, slow-moving spot and a much more strongly staining fast-moving one. After acid hydrolysis of the 'fast' spot, the following amino-acids were identified: aspartic acid, glutamic acid, serine, glycine, alanine, valine, leucine and isoleucine. The leucines were present in the highest concentration.

An acidic gastric juice from which spot "A" was absent was adjusted to pH 2.0 with dilute hydrochloric acid. After this mixture had been allowed to stand at room temperature for 16 min, spot "A" appeared as a trace on staining. The spot achieved maximum staining intensity within 1 h. Brummer *et al.* suggested that spot "A" was connected with the conversion of pepsinogen to pepsin and this they confirmed with pure hog pepsinogen.

Brummer, Seppala and Kulonen<sup>23</sup> also found a strong spot, which they again called "A", in six out of eight patients suffering from pernicious anaemia, after acidification of their gastric juices with dilute hydrochloric acid. They recognized, however, that the stomach in pernicious anaemia would be very unlikely to contain more pepsinogen than either the normal subject or the patients with simple achlorhydria. They could only suggest, therefore, that the spot obtained after the acidification of pernicious anaemia gastric juice, although chromatographically identical with spot "A", was due to another polypeptide.

The enigma of the existence of spot "A" in pernicious anaemia gastric juice was re-examined by Brummer and Seppala in 1963<sup>24</sup>, using eight patients with pernicious

anaemia, and seven patients with histamine-fast achlorhydria. Each sample of gastric juice was dialysed and the non-dialysable fraction was subjected to paper electrophoresis. On staining, bands were found which corresponded to four main protein fractions which were designated: albumin,  $M_1$ ,  $M_2$ ,  $M_3$ , and in addition there were some vague bands due to peptides. After acidification of these anacid juices, followed by electrophoresis, they found that the fraction  $M_3$  had disappeared and the peptide bands had increased in intensity. They concluded that the spot "A", which they had noticed previously in pernicious anaemia gastric juice, was probably due to polypeptides which had been freed from the albumin and mucous substances when the gastric juice had been acidified.

Heathcote and Washington<sup>22</sup> have reported recently the isolation of a peptide, from two pooled samples of normal human gastric juice, which was completely absent from the individual samples of pernicious anaemia juice which they examined. The peptide had a low  $R_F$  value in the usual chromatographic solvent systems for amino-acids and there was no evidence for the existence of a 'high streak' peptide such as was reported by Brummer and Seppala. The presence of the peptide in normal gastric juice causes marked streaking on paper chromatograms of the protein-free filtrates or dialysates. It gave a single peak in the analytical ultracentrifuge which corresponded with a molecular weight of about 1,000. Preliminary analyses indicated an amino-acid composition which was similar to, though not identical with, that of the faster moving component of Brummer *et al.*<sup>20</sup>. Washington has since reported the presence of this peptide in a third sample of normal gastric juice.

### Discussion

The results which have been obtained for the concentrations of the amino-acids in gastric juice can now be summarized. We must keep in mind, however, that in addition to the usual biological variation there are two other variables. These are, first, that the concentration may alter according to the method of production of the juice, that is, whether stimulated artificially or not, and secondly, that the method of deproteinization may affect, appreciably, the results of the analysis<sup>27,28</sup>.

Qualitatively, it would seem that almost all the common naturally occurring amino-acids which one might expect have been reported to exist in normal human gastric juice, although not always in the same sample. Taurine, citrulline and ornithine have also been reported to occur on occasions. The total amount of amino-acid nitrogen which is present in normal gastric juice has been reported to vary between 0.4 and 17.6 mg per 100 ml.

With regard to the gastric juice of pernicious anaemia patients, there are only eight reports extant and most of these refer to only a few patients. The four qualitative studies all agree on the increase in number of the amino-acids when compared with normal juice. Of the four quantitative studies, two<sup>18,19</sup> indicate a three-fold increase in the value of total amino-acids over the normal value; the third, by Hiller and Bischof<sup>26</sup>, gave individual concentrations which were about one hundred times lower than the values reported for normal gastric juice by other workers and must, therefore, be presumed to be erroneous; finally, the most recent investigation<sup>27</sup> indicates an increase of between four and five times the concentration of amino-acids in pernicious anaemia gastric juice over the normal value.

Normal gastric juice, when administered together with cyanocobalamin, orally to pernicious anaemia patients, caused remission of the symptoms<sup>24</sup> and the question is still open as to how this effect could have arisen. Could it be due, for example, to the presence of certain amino-acids in normal gastric juice, which are absent from, or present only in small amounts in, pernicious anaemia gastric juice? Simple mixtures of glutamic acid and cobalamin have

indeed been shown to be more effective than cobalamin alone<sup>25-27</sup>. At first sight, this would not seem to be a likely explanation for the improved activity because the concentration of amino-acids is greater in the pernicious anaemia juice. However, according to Ibre<sup>25</sup>, the volume of fasting juice in the normal subject may be fifteen times the volume in the pernicious anaemia patient and, accordingly, the amounts of many amino-acids, including glutamic acid, are quite likely to be present in much greater overall amount in normal gastric juice.

A further possible explanation for the improved therapeutic effect of a mixture of normal juice and cyanocobalamin could be the presence of some low molecular weight peptide. Heathcote and Mooney<sup>29,30-31</sup>, and Withey, Jones and Kilpatrick<sup>32</sup>, have reported therapeutic success in pernicious anaemia with low molecular weight peptides derived from fermentation sources. The recent discovery by Washington of a peptide in normal human gastric juice, which was found to be absent from the gastric juice of the pernicious anaemia patients examined, would seem to be of possible significance in this connexion. It would seem quite possible that such a peptide, with its strong ability to bind amino-acids, could be involved in the increase in therapeutic value of oral vitamin B<sub>12</sub> when administered with normal gastric juice. However, irrespective of the significance of these recent results in relation to the fraction of gastric juice which may be responsible for the enhanced therapeutic activity of oral vitamin B<sub>12</sub>, it is hoped that this review will be of interest to all concerned with the secretions, and pathology, of the stomach.

We thank Dr. F. S. Mooney, consultant pathologist, St. Helens Hospital, St. Helens, for his co-operation and provision of samples.

AN IMPROVED METHOD FOR THE CHARACTERIZATION OF HUMAN  
HAEMOGLOBIN MUTANTS: IDENTIFICATION OF  $\alpha_2\beta_2^{95\text{GLU}}$ ,  
HAEMOGLOBIN N (BALTIMORE)

By DR. J. B. CLEGG and DR. M. A. NAUGHTON  
Department of Biophysics

AND

DR. D. J. WEATHERALL  
Department of Medicine, Johns Hopkins University School of Medicine, Baltimore 5, Maryland

ONE of the problems during investigations of human haemoglobin mutants has been the difficulty of separating the  $\alpha$  and  $\beta$  chains in a pure form from small quantities of starting material. While chain separation is not a pre-requisite for all chemical investigations, such work can be carried out more easily on the isolated  $\alpha$  and  $\beta$  chains. The method for the separation of the peptide chains of human haemoglobin described in this communication is relatively easy to use and has an advantage over those previously reported in that it will not only give separation of the  $\alpha$  and  $\beta$  chains, but is also capable of resolving a charged mutant chain from the normal, thus enabling the globin of a heterozygous charged mutant to be fractionated into all its component chains.

A second difficulty usually encountered is the familiar one of incomplete digestion of proteins by proteolytic enzymes. Digestion of human  $\alpha$  and  $\beta$  haemoglobin chains with trypsin normally leaves a trypsin-resistant 'core' with the result that a region consisting of about 30 per cent of the molecule cannot easily be examined by fingerprinting. However, conversion of the cysteine residues of the  $\alpha$  and  $\beta$  chains to aminoethyl-cysteine by reaction with ethylenemine<sup>1</sup> has been shown by Jones<sup>2</sup> to give derivatives which no longer contain the trypsin-resistant region. Thus, fingerprints of aminoethylated  $\alpha$  and  $\beta$  chains show all the expected trypsin peptides plus additional ones due to splits at aminoethyl-cysteine.

The combination of a high-resolution chromatographic separation of the  $\alpha$  and  $\beta$  chains and the conversion of the separated chains into aminoethyl derivatives susceptible to trypsin<sup>3</sup> affords a procedure considerably more rapid and more sensitive than any previously available for studying haemoglobin mutants. With the technique described here, recoveries of the separated  $\alpha$  and  $\beta$  chains are quantitative and sufficient material for amino-ethylation and subsequent fingerprinting can be obtained from as little as 10 mg of starting globin. In addition, quantitative amino-acid analyses of peptides eluted from fingerprints of 2 mg of the digested chains have been routinely achieved.

*Isolation and characterization of the  $\beta$  chain of haemoglobin N (Baltimore).* An 8-month-old Negro female was found to have two haemoglobins by routine electrophoretic

Fig. 1. Starch-gel electrophoresis (*tris*-EDTA-borate, pH 8.6) of haemolysates containing (left to right), haemoglobin A, haemoglobins A and N, haemoglobins A and H, and haemoglobins A and J.

screening. Apart from a mild iron deficiency there were no significant haematological abnormalities either in the child or in the mother, who also carried the abnormal variant. The relevant haematological values and the proportions of normal and abnormal haemoglobins are summarized in Table 1. On starch-gel electrophoresis at pH 8.6 (Fig. 1) the abnormal haemoglobin migrated

Fig. 2. Gradient elution chromatography on carboxymethyl-cellulose of globin from haemoglobin N heterozygote

faster than haemoglobin J (Baltimore)<sup>8</sup> but slower than haemoglobin H. These electrophoretic characteristics are similar to those previously described for haemoglobin N<sup>4</sup> and the variant has therefore been designated as haemoglobin N (Baltimore). Comparative gel-electrophoresis experiments with other known haemoglobin mutants suggested that at pH 8.6 haemoglobin N (Baltimore) possesses four more negative charges per 68,000 molecular weight than does haemoglobin A. Hybridization with canine haemoglobin indicated that the abnormality in haemoglobin N (Baltimore) was in the  $\beta$  chain. Fingerprints of tryptic digests of whole haemoglobin N (Baltimore) or of isolated  $\beta^N$  (Baltimore) chain showed no detectable differences from those of haemoglobin A or normal  $\beta$  chain.

20 mg of the child's globin, prepared by 2 per cent acid-acetone precipitation of a whole red-cell lysate, was dissolved in 2 ml. of a buffer consisting of 8 M urea, 0.05 M 2-mercaptoethanol, and 0.005 M  $\text{Na}_2\text{HPO}_4$ , adjusted to pH 6.7 with phosphoric acid. The solution was dialysed at room temperature against three changes of a 50-fold excess of the same buffer for a total of 2.5 h and then applied to a 1 cm  $\times$  10 cm column of carboxymethyl-cellulose (0.7 m.equiv. g) equilibrated against the same buffer. After the column had been washed to remove any unretarded material the peptide chains were eluted at a flow rate of 1 ml./min by means of a linear  $\text{Na}^+$ -ion gradient made by mixing 100 ml. of starting buffer with 100 ml. of a buffer consisting of 8 M urea, 0.05 M 2-mercaptoethanol, and 0.03 M  $\text{Na}_2\text{HPO}_4$ , adjusted to pH 6.7 with phosphoric acid. The column effluent was monitored continuously at 280 m $\mu$  and the resulting chromatogram is shown in Fig. 2. Of the three peaks obtained, two were found at the expected elution volumes of normal  $\alpha$  and  $\beta$  chains, while the third peak emerged much earlier than normal  $\beta$  chain, indicating the presence of a more acidic  $\beta$  chain. This confirmed the findings of the hybridization experiments.

The fractions corresponding to the two  $\beta$  chains were collected and solid  $\text{KSCN}$  was added to each solution to give a concentration of 1 M. After the pH of the solutions had been adjusted to 9.2 with concentrated HCl, ethylenimine was added to a final concentration of 0.5 M (that is, a 10-fold molar excess over the 2-mercaptoethanol). The aminoethylation reactions were then allowed to proceed at room temperature until no free sulphhydryl groups were detectable by the nitroprusside test<sup>9</sup> (usually after about 2.5 h). The pH was then adjusted to 3 with concentrated HCl and the solutions passed through a 'Sephadex G-25' column equilibrated with 0.5 per cent formic acid, in order to remove urea, salts, etc. Finally, the recovered protein fractions were freeze dried.

Tryptic digests of amounts of protein greater than 10 mg were carried out at pH 9.0 for 2 h at room temperature in a radiometer pH-stat. Digestion was terminated by adjusting the pH to 4.7 and freeze-drying the solution. It was preferable to digest smaller amounts of protein in 1 per cent  $\text{NH}_4\text{HCO}_3$ , pH 8.2 (the amounts of salt introduced by the automatic procedure being sufficient to cause smearing of peptide spots when it was necessary to apply all the digest to a single fingerprint). After digestion was complete, the  $\text{NH}_4\text{HCO}_3$  was removed by repeated freeze-drying. For all the digestions the trypsin/protein weight ratio was 1/100. The dried digests were dissolved in pH 4.7 buffer (1.25 per cent pyridine, 1.25 per cent acetic acid) and aliquots corresponding to 2 mg of the original proteins were subjected to electrophoresis in this buffer on 108 cm  $\times$  57 cm sheets of Whatman No. 3 MM paper for 3.25 h at 33 V/cm in a 'Varsol'-cooled tank. After drying, the papers were chromatographed overnight in *n*-butanol, acetic acid, water, pyridine (15:3:12:10) (ref. 6). The resulting fingerprints were stained by dipping in 0.02 per cent ninhydrin-acetone and developing at 60°. Photographs of the two fingerprints are shown in Fig. 3 and the significant differences between the mutant and the normal patterns are indicated by arrows. The other slight differences are due to the varying amounts of partially split peptides.

The fingerprint of the mutant  $\beta$  chain is characterized by the absence of peptides  $\beta\text{Tp}10$  and  $\beta\text{Tp}11$  and by the appearance of a new peptide which has a distinctive yellow colour. Since  $\beta\text{Tp}10$  also gives a yellow colour with ninhydrin, these observations suggest that the mutant peptide is a combination of  $\beta\text{Tp}10$  and  $\beta\text{Tp}11$ . (No tryptic cleavage at the aminoethyl-cysteine residue in  $\beta\text{Tp}10$  has been found, presumably because aspartic acid is the adjacent amino-acid, the sequence in this region being AECys (aminoethyl-cysteine)<sup>12</sup>-Asp<sup>14</sup>-Lys<sup>15</sup> (ref. 7). This absence of a split at AECys<sup>12</sup> was previously

Fig. 3. Fingerprints of tryptic digests of AEM(Baltimore) (above) and normal AEM chains (below)

reported by Jones<sup>1</sup>.) The peptides to be analysed were cut from the fingerprints and eluted with 6 N HCl into 100  $\mu$ l. capillary disposable pipettes by the method described by Sanger and Tuppy<sup>2</sup>. Collection of 30–40  $\mu$ l. was sufficient to ensure complete removal of the peptide from the paper. The tubes were then sealed, and heated at 105° for 18 h. After hydrolysis, the contents of the tubes were washed into 0.5 ml. of distilled water and applied directly to a 'Technicon' 5-column amino-acid analyser. This made it unnecessary to dry down the hydrolysates, a procedure which has been shown to reduce the yield of amino-acids, possibly because of further reaction with ninhydrin<sup>3</sup>. Table 2 gives the amino-acid analysis and composition of the mutant peptide. From this it is apparent that the lysine residue (95) of  $\beta$ Tp10 has been replaced by glutamic acid (or glutamine), with the result that a conjugate peptide,  $\beta^N$ Tp10–11, is formed by tryptic digestion of the mutant  $\beta^N$ (Baltimore) chain. The evidence for a lysine to glutamic acid (rather than glutamine) change at position 95 in the haemoglobin N (Baltimore)  $\beta$  chain is provided by the starch-gel electrophoresis findings of a difference of four negative charges between haemoglobin N (Baltimore) and haemoglobin A. It explains why the mutant peptide  $\beta^N$ Tp10–11, occurring as it does in the 'core' region of the  $\beta$  chain, was not detected on the original fingerprints of tryptic digests of haemoglobin N (Baltimore) or of the isolated  $\beta^N$ (Baltimore) chain which had not been reacted with ethyleneimine.

Table 2. AMINO-ACID ANALYSIS AND COMPOSITION OF Amino-ACID CHAIN PEPTIDES

Amino-acid	Amino-acid (Baltimore)			Amino-acid (ref. 7)		
	$\beta^N$ (Baltimore)	Tp 10–11		$\beta^N$ Tp10	$\beta^N$ Tp11	$\beta^N$ Tp10 + $\beta^N$ Tp11

Overall recovery of Amino-acid (Baltimore) Tp10–11 was 24 per cent of amount originally applied to the fingerprint.

In accordance with the recommended nomenclature<sup>10</sup>, haemoglobin N (Baltimore) is designated as  $\alpha_2\beta_1^{N95}$ .

The procedure outlined in this article has the following advantages over those previously described:

(1) The chromatographic system enables globin from a heterozygous charged mutant to be resolved quantitatively into all its component chains, thus simplifying subsequent chemical investigations. In addition, the high resolution achieved during chromatography eliminates the need for hybridization experiments to determine in which chain an amino-acid substitution is located. (It should be mentioned that the pH of the chromatographic system is not critical and can be varied from at least pH 6.5 to 7.2, the actual choice depending largely on the nature of the mutant globin to be fractionated and the degree of resolution required. As an example of this flexibility, Fig. 4 shows a separation of 11 mg of sickle-trait globin into  $\beta^A$ ,  $\beta^S$  and  $\alpha$  components at pH 7.2.)

(2) All the tryptic peptides of the amino-ethylated  $\alpha$  and  $\beta$  chains can be resolved by fingerprinting.

(3) Quantitative amino-acid analysis of these peptides can be determined on samples obtained by elution from a ninhydrin-stained fingerprint of as little as 2 mg of digested chain.

## A MODIFIED 'ASEPTIC ADDITION' ASSAY PROCEDURE FOR THE MEASUREMENT OF SERUM 'FOLIC-ACID' ACTIVITY

By T. A. HARPER\*

Department of Pathology, Wythenshawe Hospital, Manchester

THE 'folic-acid' activity of serum is now recognized as a reliable index of the folate state of an individual and is measured by a micro-biological assay technique with the organism, *Leuobacillus casei*. A reliable and accurate method, which is not time-consuming, is necessary because the investigation is now no longer restricted to the elucidation of the aetiology of a megaloblastic

anaemia and is being applied to patients suffering from a variety of diseases.

The 'aseptic addition method' of Herbert and Zalusky<sup>1</sup> fulfils the foregoing criteria. In this method, serum extraction is not used and the serum is added directly to the prepared assay tubes immediately before inoculation with the organism. However, further simplification of this technique is possible without detracting from the value of the test.

\*Address from September 13, 1965: Department of Pathology, St. Catherine's Hospital, Birkenhead.

The purpose of this article is to describe a modified 'aseptic addition' assay procedure for measuring the 'folio-acid' activity of serum.

**Method.** The assay medium is the double-strength assay medium of Waters and Mollin<sup>1</sup> with additional L-tryptophan (25 mg/100 ml.).

The stock solution (0.4 mg/ml.) of pteroyl-glutamic (folio) acid in 20 per cent ethanol is stored in an amber bottle in the refrigerator. It is used to prepare the standard curve.

Serum, without added ascorbic acid and in which no haemolysis is evident, is stored at  $-20^{\circ}\text{C}$ .

Ascorbic acid (2 mg/ml.) is dissolved in water just before use, to provide 'ascorbate water'.

De-ionized water from an 'Elgastat' de-ionizer is used in the preparation of all solutions.

*Lactobacillus casei* (ATCC 7469, NCIB 8010) is maintained as a stab culture in micro-culture agar (Difco) and sub-cultured weekly. The inoculum is prepared according to the method of Chanarin and Berry<sup>2</sup>, but sterile physiological saline is used instead of single-strength assay medium to wash the bacterial deposit.

The stock pteroyl-glutamic acid solution is diluted in water to a working solution of 0.4  $\mu\text{g}/\text{ml}$ . immediately before use. A duplicate set of tubes (2 ml. in each) containing 0.0, 0.1, 0.2, 0.4 and 0.8  $\mu\text{g}$  of folio acid is prepared from the working solution; 2 ml. of double-strength assay medium is added to each tube and the tubes are closed with aluminium caps. The final folio acid concentrations are 0.0, 0.025, 0.05, 0.1 and 0.2  $\mu\text{g}/\text{ml}$ . The tubes are autoclaved at 10 lb./in.<sup>2</sup> for 10 min.

For each serum to be assayed, 1.96 ml. of ascorbate water is added to each of two tubes containing 2 ml. of double-strength assay medium. After closing the tubes with aluminium caps, they are autoclaved at 10 lb./in.<sup>2</sup> for 10 min. On cooling, 0.04 ml. of serum is added to each of the two tubes (the serum dilution is 1:100). All the tubes, including those of the standard curve, are inoculated with one drop of the *L. casei* inoculum and then incubated at  $37^{\circ}\text{C}$  for 18 h.

The turbidities are measured in a photo-electric colorimeter ( $\lambda = 510\text{--}590$ ). A mixture of the duplicate 0.0 tubes of the standard curve is used to 'zero' the instrument. (An uninoculated serum blank tube is not necessary.)

The turbidities of the folio acid standard curve are plotted on arithmetic graph paper against the concentration of folio acid in  $\mu\text{g}/\text{ml}$ . The 'folio-acid' activity of the serum is calculated from the resultant curve, taking into consideration the serum dilution. For greater accuracy, sera with 'folio-acid' activities below 2.5  $\mu\text{g}/\text{ml}$ . and above 20  $\mu\text{g}/\text{ml}$ . are re-assayed at lower and higher serum dilutions, respectively.

**Effect of ascorbic acid on the growth of *L. casei*.** Two sets of the standard curve were set up in duplicate; one set was prepared in water and the other set in ascorbate water (2 mg/ml.). After being autoclaved, the tubes were inoculated with the *L. casei* inoculum and then incubated at  $37^{\circ}\text{C}$ . The turbidities were measured using a 'medium blank', an uninoculated single-strength assay medium, to 'zero' the instrument.

Table 1. EFFECT OF ASCORBIC ACID ON GROWTH OF *L. casei*

	Folio acid in $\mu\text{g}/\text{tube}$				
Standard curve	0.0	0.1	0.2	0.4	0.8
Turbidities in water	45	60	70	85	95
Turbidities in ascorbate water	44	58	73	85.5	99

Instrument set with 'medium blank'.

The results are indicated in Table 1. They show that, at the concentration used, the ascorbic acid has no effect, either stimulant or depressant, on the growth of *L. casei*.

**Effect of phosphate buffer on the growth of *L. casei*.** Water and phosphate buffer (0.1 M; pH 6.1) were first autoclaved at 10 lb./in.<sup>2</sup> for 10 min. (A) Three sets of

Table 2. EFFECT OF PHOSPHATE BUFFER ON THE GROWTH OF *L. casei*

A. Tubes containing no folio acid			
Water	2.0 ml.	1.6 ml.	0.0 ml.
Phosphate buffer	0.0	0.4	2.0
Assay medium	2.0	2.0	2.0
Turbidities	45	50	65

Instrument set with 'medium blank'.

B. The standard curve				
Standard curve	0.0	Folio acid in $\mu\text{g}/\text{tube}$		
		0.1	0.2	0.4
Turbidities in water	45	60	70	85
		15	25	40
Turbidities in buffer	65	78	86	103
		18	21	38

Instrument set with 'medium blank'.

five tubes were set up. 2 ml. water was added to each tube of the first set; 1.6 ml. water and 0.4 ml. buffer was added to each tube of the second set; 2 ml. buffer was added to each tube of the third set. 2 ml. double-strength assay medium was then pipetted into all the tubes. (B) Two sets of the standard curve were prepared in duplicate; water was used for one set and the buffer for the second set. All the tubes of 'A' and 'B' were capped, autoclaved, inoculated and incubated at  $37^{\circ}\text{C}$ . The turbidities were measured after 18 h, using a 'medium blank', an uninoculated single-strength assay medium, to 'zero' the instrument.

The results are given in Table 2 'A' and 'B'. They demonstrate that there is increased growth of *L. casei* in the presence of phosphate buffer and that the inclusion of an inoculated 'buffer blank' tube is necessary.

**The *L. casei* activity of stored serum.** The *L. casei* activity of four sera, without and with ascorbic acid (5 mg/ml.), which had been in storage at  $-20^{\circ}\text{C}$  for more than 3 months, was studied. The modified 'aseptic addition' method was used with and without the ascorbate water.

The results are given in Table 3. They show that the *L. casei* activity of the 'stored serum without ascorbic acid' was similar to that of the 'stored serum with ascorbic acid' when ascorbate water was used, but was less when water replaced the ascorbate water in the assay procedure.

Table 3. *L. casei* ACTIVITY OF STORED SERUM

Mod. 'As. Ad.' method using	Serum With ascorbic acid		Without ascorbic acid	
	Water	Ascorbate water	Water	Ascorbate water
1	48	47	28	51
2	107	106	85	104
3	97	94	70	98
4	75	76	60	72

Instrument set with 'medium blank'.

**Comparison of the *L. casei* activity of serum measured by the method of Waters and Mollin<sup>1</sup> and the modified 'aseptic addition' method.** Twenty paired sera, that is, sera with and without ascorbic acid, were used. The assay procedure of Waters and Mollin<sup>1</sup> was used on the serum containing ascorbic acid (5 mg/ml.); an inoculated 'buffer blank' tube, containing an equivalent amount of autoclaved ascorbate phosphate buffer, was included for the purpose of setting the instrument when the turbidities of these tubes were measured. The modified 'aseptic addition' method was used on the sera not containing ascorbic acid; an inoculated 'water blank' tube, single-strength assay medium in water, was included with these tubes to set the instrument for measuring the turbidities.

The resultant turbidities of the corresponding sera are given in Table 4. They show that the *L. casei* activity of the corresponding sera measured by the two assay procedures is essentially similar.

Table 4. COMPARISON OF SERUM *L. casei* ACTIVITY MEASURED BY THE MODIFIED 'ASEPTIC ADDITION' METHOD AND THE METHOD OF WATERS AND MOLLIN

Mod. 'As. Ad.' method	123	49	45	112	75	74	59	160	80	55
Waters and Mollin method	127	53	42	109	70	77	50	145	35	52
Mod. 'As. Ad.' method	59	81	88	118	77	58	94	40	83	60
Waters and Mollin method	65	92	85	109	81	62	90	45	39	55

**Discussion.** The modified 'aseptic addition' method described in this article differs in certain respects from

that of Herbert and Zalusky<sup>1</sup>. The assay medium of Waters and Mollin<sup>2</sup> with additional L-tryptophan is used instead of the assay medium of Herbert<sup>4</sup>; the final volume in each assay tube is reduced from 10 ml. to 4 ml.; ascorbate water (2 mg/ml.) replaces ascorbate phosphate buffer (10 mg/ml.; pH 6.1).

A number of factors influenced the decision to use a final volume of 4 ml. in each assay tube. The most important was that with this volume it was possible to measure the 'folio/acid' activity on a very small sample of serum (0.04 ml.) without loss of accuracy which would have been the case with the high dilution necessary with a final volume of 10 ml. The use of a small volume of serum is particularly of great value in paediatric cases and in those adults in whom venepuncture is difficult.

Herbert<sup>4</sup> found that ascorbic acid and phosphate buffer stimulated the growth of *L. casei* and consequently used ascorbate phosphate buffer in the preparation of both the serum tubes and the standard curve tubes. Waters and Mollin<sup>2</sup> demonstrated that ascorbate phosphate buffer had no effect on the growth density of the organism. Ball and Giles<sup>5</sup>, using the method of Waters and Mollin for measuring serum *L. casei* activity, added ascorbic acid (1 mg/ml.) as a routine to the double-strength assay medium in order to stimulate the growth of the organism and to stabilize the relationship between the serum tubes and the standard curve tubes. The investigations reported here showed that, whereas the growth of *L. casei* was increased in the presence of phosphate buffer, ascorbic acid in the concentration used had no effect.

The phosphate buffer solution was eliminated from the modified 'aseptic addition' method because the buffering capacity of the assay medium was considered adequate and consequently its inclusion in the serum tubes and the standard curve tubes was regarded as superfluous.

In view of the finding that ascorbic acid, in the concentration used, has no effect on the growth of the organism, the ascorbate water is not used in the preparation of the standard curve. Its use in the serum tubes is essential because ascorbic acid is not added to serum either before or after storage. However, those who prefer to add ascorbic acid (5 mg/ml.) to the serum prior to storage may do so without affecting the eventual result, for the amount of ascorbic acid in the assay tube is still insufficient to destroy folate. Using the method as described, the tedium of weighing our ascorbic acid for each serum sample received, and the storage of the samples as paired sera, were avoided. The concentration of ascorbic acid was reduced to 2 mg/ml., for even at this concentration sufficient remains after autoclaving to restore any *L. casei* activity 'lost' in the stored serum.

The lability of the *L. casei* activity of serum is an established fact, as is the value of ascorbic acid in respectively preventing and protecting its decline and destruction. Herbert<sup>4</sup>, however, considered that the activity was stable in the frozen state. On the other hand, the results of an investigation by Waters and Mollin<sup>2</sup>, which were substantiated by Chanarin and Berry<sup>3</sup>, clearly demon-

strated a decline in the activity in serum stored without added ascorbic acid at -20° C; they also showed that the 'lost' activity could be restored by the addition of ascorbic acid (5-15 mg/ml.) to the serum after storage. The results of the investigation reported in this article showed that with the modified 'aseptic addition' method there was no difference in the activity of serum stored with or without ascorbic acid if ascorbate water was used in the serum assay tubes, but that there was a difference if the ascorbate water was replaced by water. An 'aseptic addition' method, using ascorbic acid in the serum assay tubes, thus masks any decline of *L. casei* activity which may have occurred in the serum during storage at -20° C, by restoring it to its original level during the assay itself.

Herbert<sup>4</sup> emphasized that stringent aseptic techniques were not essential when handling the serum. He did not regard bacterial contamination as a problem because of the rapid growth of *L. casei* and the quantity of lactic acid produced during the assay. His experience was confirmed in this laboratory by sub-culturing on to blood agar plates a number of the serum assay tubes before the measurement of their turbidities; these sub-cultures were incubated at 37° C and examined after 18 h; they revealed no contamination with other organisms.

Before adopting, it was essential to evaluate the modified 'aseptic addition' method, especially with the view of deciding on the necessity of determining the normal range of serum 'folio/acid' activity for the method. Comparison of *L. casei* growth densities obtained by the modified 'aseptic addition' method and the method of Waters and Mollin on paired sera showed that the results were comparable; Herbert<sup>4</sup> observed a similarity between his results and those of Waters and Mollin. Because of these observations and findings, the figures reported by Herbert and Zalusky<sup>1</sup> are accepted for the modified 'aseptic addition' assay procedure. Levels of serum 'folio/acid' activity below 3 µg/ml. are regarded as diagnostic of folate deficiency, while levels between 3 and 4.9 µg/ml. are strongly suggestive; levels between 5 and 7 µg/ml. are considered to be equivocal and the normal range is given as 7-16 µg/ml.

The modified 'aseptic addition' assay procedure is less time-consuming than other methods; a small volume of serum only is required and this enables the technique to be applied to paediatric cases, without the necessity of resorting to venepuncture. *Lactotacillus casei* is an organism which is sensitive to many antibiotics *in vitro*, including the anti-tuberculous drugs, and consequently it is advisable not to carry out the assay on patients receiving antibiotics.

I thank Dr. K. V. Lodge for her advice and help.

## MECHANISM OF INTESTINAL ABSORPTION IN MAN

By I. McCOLL and Dr. J. A. NISSIM

Departments of Surgery and Pharmacology, Guy's Hospital Medical School, London, S.E.1

ABOUT six years ago, a new kind of inhibitor of intestinal absorption was discovered, namely, cetrinide<sup>1</sup>. This substance blocked the absorption of a variety of nutrients, but it also caused reversal of flow of glucose, from the blood to the intestinal lumen. In the

rabbit and guinea-pig, this reversal occurred at a concentration of the drug which left the absorption of methionine and butyrate undiminished, thus indicating direct interference with the active transport of glucose. The examination of the mode of action of this and other

compounds resulted in a new theory of the mechanism of intestinal absorption, the main features of which were summarized recently<sup>1</sup>. In the course of these investigations, striking species and strain variations came to light, and, hence, it appeared particularly important to find out what actions the various intestinal inhibitors possessed in man, and whether the new concepts regarding the mechanism of intestinal absorption applied to our species with parallel validity. Experiments were planned along lines indicated by these previous studies in animals, and a preliminary account of the results is given in this article.

The experiments were carried out with complete safety on volunteers undergoing abdominal operations for a variety of reasons. After washing through a length of jejunum, beginning at a point 15 cm distal to the duodeno-jejunal flexure, with 0.9 per cent (w/v) saline at 37° C, four segments, 12 cm in length each, were firmly but gently clamped off, forming four completely isolated sacs. Into these sacs were injected 50 ml. of saline-nutrient solutions, containing 0.9 per cent sodium chloride and 0.2 per cent (w/v) of D-glucose, sodium butyrate and DL-methionine, and the effect of different concentrations of the drugs ( $0.5 \times 10^{-4}$  –  $8 \times 10^{-4}$ ) was investigated. In most experiments, the four sacs contained cetrinide, phloridzin, cetrinide + phloridzin and a control solution without drug. The order of sacs in relation to the drug used was varied, so as to isolate the effect of distance from the duodeno-jejunal flexure on absorption by an

analysis of variance. The solutions were withdrawn after an absorption interval of 5 min, the volume measured, and estimations carried out on glucose, butyrate and methionine as previously<sup>1</sup>. The percentage absorption of the nutrients was calculated from the amount of nutrient recovered out of the total 100 mg put in. During the experiment, the segments were kept as close to normal body temperature as possible. The duration of the whole experiment averaged 11 min. The injection tracks were sealed with fibrin foam at the end. We shall confine ourselves to an analysis of the effects of the drugs on glucose absorption and some comments on the absorption of butyrate and methionine. A more detailed account will follow elsewhere.

The mean percentage absorption,  $\pm$  S.E., for glucose, butyrate and methionine in 36 control sacs was  $52.46 \pm 2.27$ ,  $44.27 \pm 2.37$ , and  $40.17 \pm 1.92$  respectively. The design of the experiment, and the inclusion of a control sac in each subject, was fully justified by the results. As anticipated, the variation between experiments on different individuals was such as to preclude the establishment of any particular effect at a satisfactory significance level, from a small number of experiments. This is evident from Table 1, where the mean percentage absorption values of glucose are shown for different concentrations of the drugs. There is probable stimulation of absorption at  $10^{-4}$  cetrinide, and inhibition at larger doses. From the bottom line, which gives the mean percentage absorption for each column, one may conclude greater inhibitory effect for phloridzin than for cetrinide, and synergistic inhibition when the drugs were combined. It is clear that no satisfactory significance for regression of dose on response would emerge from these data, nor for any of the other usual analytic comparisons. On presenting the results as the difference in the percentage absorption for each sac from its control value on the same subject, however, we obtain a strikingly different picture (Table 2 and Fig. 1). We are now able to demonstrate linear regression and draw other conclusions with a high order of certainty. The importance of this experimental design in our study is thus established with little doubt.

The results of an analysis of variance for the three dose-response lines of cetrinide, phloridzin, and cetrinide + phloridzin are given in Table 3, together with the dose-response formulae. Deviation from regression was

not significant for any of the lines, nor was the difference between slopes. The potency ratios showed the inhibitory effect of phloridzin to be 2.87 times that of oestrime, though this difference must be exaggerated by the stimulating effect of oestrime at low concentrations. The effect of the two drugs together was greater by a factor of 4.47 as compared with the effect of oestrime alone, and by 1.73 as compared with phloridzin. All the differences mentioned showed a high order of significance except the latter, that is, the difference in potency between phloridzin and oestrime + phloridzin, for which  $P$  was only just smaller than 0.1. However, the parallel greater activity of the mixture, which was also obtained with regard to butyrate and methionine absorption, lends greater significance to this result. Further, Table 3 shows no significance for order of segment on intestinal absorption.

Increased absorption of glucose was obtained at the lower concentrations of oestrime,  $0.5 \times 10^{-3}$  and  $10^{-4}$ . This is in agreement with the results obtained previously in animals<sup>1,2</sup>. Since regression evidently stops at  $10^{-4}$  oestrime, the lower concentration of  $0.5 \times 10^{-4}$  was not included in the calculation of the dose-response formula, nor in the analysis of variance. A 't' test carried out for the mean difference of these two groups (23 expts.) from their control established stimulation at the lower doses of oestrime with a  $P \approx 0.001$ . A similar increase of butyrate absorption at these doses occurred with a mean of 4.8 (= 11 per cent), which gave a 't' test with  $P < 0.05$ , but the difference was smaller for methionine absorption with a mean of 2.2 (= 5.5 per cent), for which no statistical significance was obtained.

The present investigation was restricted to concentrations of  $8 \times 10^{-4}$  or less, but in spite of this limitation, significant linear regression with dose was obtained for all three sets of experiments. The results in man reinforce in several aspects those obtained in animals<sup>1,2</sup>, but there are nevertheless some interesting differences. The stimulation of glucose and butyrate absorption with low doses of oestrime was parallel to the stimulation previously demonstrated with the same substance in the mouse and rat, and may be concluded to have the same significance, namely, that it is the result of the combination of oestrime with mobile intracellular proteins acting as carriers for the different nutrients. This conclusion follows from the analysis of the stimulant effect of inhibitors at low concentrations, previously shown<sup>1,2</sup> to require several mobile protein carriers, which can only be accommodated in the intracellular plasma. Presuming that, as in the mouse and rat, phloridzin acts primarily on a first receptor in relation to a portal of entry through the cell membrane, the site of action of oestrime would constitute the second receptor in this two-stage mechanism of intestinal absorption. Within the present dose range, no stimulation of glucose absorption was obtained with low concentrations of phloridzin, though this may be demonstrated at still lower concentrations, if phloridzin exhibits

affinity for the second receptor as in the mouse. Stimulation of the absorption of butyrate of about 10 per cent, and of methionine of about 15 per cent, was, however, obtained with phloridzin, so that combination with the protein carriers of butyrate and methionine may be presumed.

As in the mouse and rat, and contrary to its effect in the rabbit and guinea-pig, phloridzin showed greater potency in man than did oestrime. On the other hand, the synergistic effect exhibited when the two drugs were combined was of a much smaller order than that obtained in the mouse and rat. In these two species, synergism was shown to require conservation of phloridzin from silent receptors through displacement by oestrime, in addition to logarithmic synergism through action on two distinct receptors in series. The weaker synergism obtained in man suggested at first that only logarithmic synergism may be involved, due to the combined action of phloridzin at the first receptor and of oestrime at the second receptor. A theoretical curve based on a hypothesis of logarithmic synergism can be constructed from the two dose-response formulae for phloridzin and oestrime. The results give reasonable agreement with experiment for the three highest doses of the combined drugs, but show striking deviation at the lowest doses, where logarithmic synergism gives stimulation of absorption (Table 3). Furthermore, no stimulant effect was obtained when the two drugs were used together at the lower concentrations of any of the three nutrients. This suggests strongly that conservation of phloridzin from silent receptors must still be a factor to be reckoned with, in addition to the expected logarithmic synergism, though this conservation must be of considerably smaller value than in the mouse, and assumes importance only at lower concentrations of the drugs.

In summary, the present investigation of the effect of oestrime and phloridzin on intestinal absorption in man suggests that these compounds have activities similar to those already demonstrated in the mouse and rat. Both the stimulation at lower doses of oestrime and the potentiation between oestrime and phloridzin suggest that the theory previously advanced for the mechanism of absorption in the lower species also holds in man. Besides a portal of entry, which in the case of glucose and butyrate is blocked by phloridzin, the function of active transport against a gradient is vested with a spectrum of intracellular proteins, which have overlapping but distinctive affinities. Hence, detailed study of these proteins, involving their affinities to nutrients and drugs and their fractionation and identification, constitutes the logical next step in the further elucidation of the mechanism of absorption.

## NOREPINEPHRINE METABOLISM IN HYPERTROPHIED RAT HEARTS

By DR. JOSEF E. FISCHER, W. DALE HORST and IRWIN J. KOPIN

National Institute of Mental Health, National Institutes of Health, U.S. Department of Health, Education and Welfare, Bethesda, Maryland

CIRCULATING norepinephrine is initially inactivated largely by being taken up and bound in sympathetic nerve endings<sup>1</sup>. In certain pathological conditions such as hyperthyroidism, an increased sensitivity to norepinephrine has been suggested on clinical grounds. It has afterwards been shown that, in hyperthyroid rats, because of blood flow changes a greater portion of intravenously administered catecholamine reaches the enlarged

hearts of hyperthyroid animals, but the hypertrophied myocardium is not able to bind more administered norepinephrine than normal hearts<sup>2</sup>. There probably is no increase in sympathetic nerve supply as the heart hypertrophies. It was therefore suggested<sup>3</sup> that the net decrease in density of these important catecholamine-inactivating structures was the reason that less norepinephrine is bound per gram of heart muscle in hyperthyroidism<sup>3,4</sup> and

that this contributes to the supersensitivity to catecholamines.

Cardiac hypertrophy accompanies a variety of clinical entities. The sympathetic nervous system is thought to play an important part in cardiovascular physiology but presumably is anatomically unaltered in cardiac hypertrophy. It was therefore desirable to study the effects of cardiac hypertrophy on the disposition of norepinephrine, in the absence of the hypermetabolic state of hyperthyroidism.

Male Sprague-Dawley rats, weighing 140-160 g, were anaesthetized with ether, and the abdominal aortae constricted above the superior mesenteric artery with a single No. 40 cotton ligature. The ligature was tightened while a 20-gauge hypodermic needle was held adjacent to the aorta, to obtain consistency in the degree of constriction.

Two months later, a similar procedure was performed on litter mates of the first group. Operative mortality was 5-10 per cent. In another group of rats the ligature was tightened over a 23-gauge needle, but only a small number of rats survived this severe degree of aortic constriction.

Sham-operated animals of the same age and weight served as controls. Animals were weighed periodically, and any animals with evidence of infection (poor weight gain) were discarded.

In the following experiments, endogenous and administered labelled norepinephrine in the myocardium, as well as the fraction of the cardiac output perfusing the heart, were estimated in each animal. Blood flow was estimated using the  $^{45}\text{K}$  technique of Sapirstein<sup>4</sup>.

Two or four months after aortic constriction, the experimental animals and their sham-operated controls each received 90  $\mu\text{C}$  d,l-7-norepinephrine- $^3\text{H}$  (20 mc/mg, New England Nuclear Corp.) intravenously and were killed by decapitation 2 min, or 1, 6, or 24 h later. Twenty seconds before decapitation, 1  $\mu\text{C}$   $^{45}\text{K}$  (as KCl, adjusted to 4 mequiv./ml.) was injected intravenously. Hearts were rapidly removed, cooled on ice, weighed, and assayed for  $^{45}\text{K}$  in a gamma ( $\gamma$ ) well counter. A  $^{45}\text{K}$

standard representing 1 per cent of the injected dose was assayed periodically to correct for  $^{45}\text{K}$  decay. Hearts were then homogenized in 10 volumes of cold 0.4 N perchloric acid and assayed for tritiated<sup>5</sup> as well as endogenous<sup>6</sup> norepinephrine. The 5 animals which survived aortic constriction to the diameter of a 23-gauge needle constituted a single group killed 2 min after intravenous injection of  $^3\text{H}$ -norepinephrine.

Cardiac weights of the animals with aortic constriction to a 20-gauge needle ( $1,284 \pm 24$  mg) were significantly greater ( $P < 0.001$ ) than those of the sham-operated controls ( $934 \pm 9$  mg).

None of the hearts of the sham-operated animals exceeded 1 g. The hearts of animals with aortic constriction (over a 20-gauge needle) were divided into two groups on the basis of weight. Hearts weighing between 1 and 1.25 g were classified as mildly hypertrophied, and those weighing 1.25-1.50 g as moderately hypertrophied. Severe cardiac hypertrophy ( $> 1.50$  g) was seen only in rats with marked (23-gauge needle) aortic constriction.

The body weight of rats with aortic constriction ( $349 \pm 18$  g) was not greater than the sham-operated controls ( $358 \pm 15$  g). There was no evidence of congestive heart failure, pulmonary congestion, hepatomegaly, effusions, cyanosis, or oedema in any of the animals.

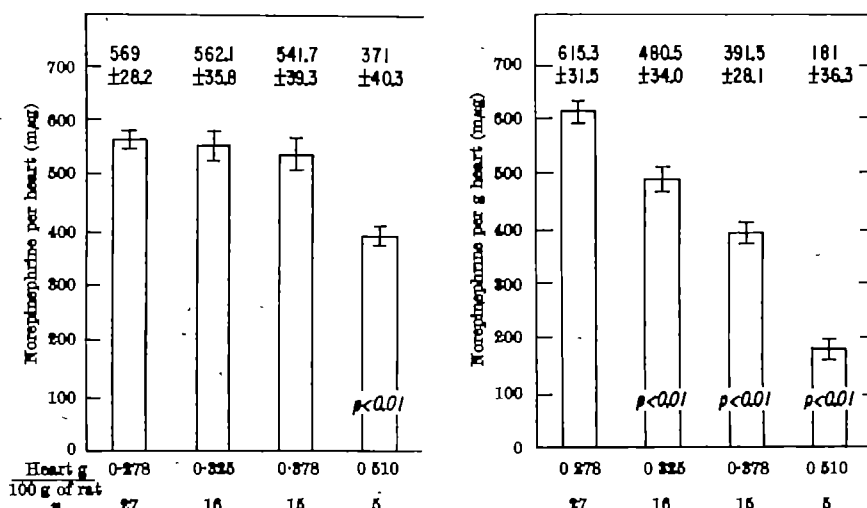

Fig. 1. Norepinephrine content of normal and hypertrophied rat hearts, expressed in terms of content (left histogram) and concentration (right histogram)

Myocardial concentration of norepinephrine was diminished in hypertrophied hearts, but with mild or moderate cardiac hypertrophy the total norepinephrine content was unaltered (Fig. 1). This is consistent with the view that norepinephrine is largely confined to the sympathetic nervous tissue and that this tissue is unaltered with myocardial hypertrophy. When the heart was markedly hypertrophied, the total norepinephrine content, as well as concentration, was diminished.

The total content of  $^3\text{H}$ -norepinephrine two minutes after administration of the labelled catecholamine was not altered in mildly or moderately hypertrophied hearts, but was decreased in markedly hypertrophied hearts (Table 1); the concentration was, however, reduced in all cases and was inversely related to the degree of hypertrophy.

When  $^{42}\text{K}$  is injected intravenously, the labelled ion reaches the various organs in proportion to the percentage of the cardiac output perfusing the organ. Although there is not complete extraction of  $^{42}\text{K}$  by the tissue, a large portion delivered to each organ remains there, presumably because of the large intracellular store of potassium and the rapid equilibrium of intracellular and circulating potassium. The percentage of injected  $^{42}\text{K}$  found in an organ has been used to estimate the proportion of cardiac output perfusing the organ<sup>4</sup>.

With myocardial hypertrophy subsequent to abdominal aortic stenosis the proportion of injected  $^{42}\text{K}$  found in the heart, and presumably the proportion of the cardiac output perfusing this organ, increases (Table 1) so that no significant difference was found in the proportion of cardiac output perfusing each gram of normal or hypertrophied heart. The proportion of administered norepinephrine- $^3\text{H}$  delivered to normal and hypertrophied hearts would be expected to parallel the uptake of  $^{42}\text{K}$ . Thus, although each gram of hypertrophied myocardium received about the same amount of injected norepinephrine- $^3\text{H}$  as did normal heart muscle, two minutes later there was a lower concentration of the tritiated catecholamine in the moderately and markedly hypertrophied hearts.

Initially the total amount of tritiated norepinephrine present in moderately hypertrophied hearts was the same as in hearts of normal animals, but less of the labelled catecholamine was present 6 or 24 h later (Table 2). These results suggest that there is a more rapid rate of turnover of norepinephrine in this group. The increased turnover rate in hypertrophied hearts may be the consequence of marked sympathetic overactivity or diminished ability to retain catecholamines. Since the norepinephrine concentration is unaltered in moderate hypertrophy (Fig.

1), it appears that replacement can keep pace with increased net loss of catecholamine and implies an increased rate of norepinephrine synthesis. With marked hypertrophy (Fig. 1) or cardiac failure<sup>5</sup>, the endogenous norepinephrine content of the left ventricle is diminished. The diminished norepinephrine content indicates that replacement no longer keeps pace with loss. This may be a consequence of further increase in loss of norepinephrine or a diminished rate of synthesis. Further increase in loss of norepinephrine could be a consequence of further increase in sympathetic nerve activity, or diminished rebinding of norepinephrine. The data suggest that the second mechanism may be operative, for in severely hypertrophied hearts there is a decrease in uptake of tritiated norepinephrine not related to blood flow (Table 1).

Only about 20 per cent of the norepinephrine content of the heart is derived from the circulation<sup>6</sup>. Thus, while decreased uptake could account for a small portion of the diminished catecholamine content, this could not account for the observed 35 per cent decrease in total norepinephrine content of markedly hypertrophied hearts.

When norepinephrine is released from sympathetic nerve endings, a large portion of the neurotransmitter is inactivated by being re-bound in the nerve ending. This conserves norepinephrine and diminishes the need for synthesis in maintenance of the catecholamine stores. If the mechanism for binding of norepinephrine were impaired, the net rate of norepinephrine loss would be increased, especially if increased sympathetic nerve activity occurred. The diminished uptake of exogenous norepinephrine suggests an impaired binding mechanism, and this may partially explain the increased norepinephrine loss.

With moderate hypertrophy an increased rate of synthesis might keep pace with the increased loss associated with the more rapid turnover rate that has been demonstrated. With severe hypertrophy or cardiac failure, however, metabolic derangements might prevent the maintenance of a balance between synthesis and loss, resulting in a diminished store of norepinephrine.

## POST-NATAL ORIGIN OF MICRONEURONES IN THE RAT BRAIN

By PROF. JOSEPH ALTMAN and DR. GOPAL D. DAS

Psychophysiological Laboratory, Massachusetts Institute of Technology, Cambridge, Massachusetts

**M**ITOTIC neurones are seldom, if ever, seen after birth in the brains of mammals, from which it is commonly concluded that neurogenesis is a pre-natal phenomenon. This conclusion is not often questioned, even though post-natal neurogenesis in some brain structures has been well established for some time. Thus it was recognized in the nineteenth century<sup>1-3</sup> that a class of small nerve cells, the granule cells, shows a high rate of proliferative activity in the cerebellar cortex in young animals. Likewise, good quantitative evidence was obtained some time ago<sup>4</sup> of an increase in the total number of nerve cells in the cerebral cortex of rats up to the 20th day after birth. In this article we shall describe recent autoradiographic evidence from our laboratory which shows clearly that a large proportion of the short-axoned neurones present in various brain structures are formed after birth in the rat.

In these investigations we injected rats systemically with tritiated thymidine. Thymidine is a specific precursor of chromosomal DNA and it is incorporated into cell nuclei only when new DNA is formed by cells preparing for multiplication<sup>5</sup>. When animals are injected with tritiated thymidine, the cells proliferating at the time of injection tend to incorporate the administered radiochemical and they thus become 'tagged'. The radioactively labelled cells are then easily identified with fine-resolution autoradiography. Moreover, by killing animals after varying periods of survival following the injection, a time-lapse record may be obtained of the fate of the originally labelled cells, such as the kinetics of their re-multiplication, and their migration and transformation.

In a pilot study<sup>6</sup> we made stereotaxic lesions in the lateral geniculate body in rats and then injected a small dose of tritiated thymidine into the lesion area. The

Fig. 1. Low-power photomicrograph of a galloxyanin-chromalum-stained autoradiogram of a brain section from a rat injected with tritiated thymidine at the age of 6 h and killed 24 h later. Black dots are the labelled cells. A, Ammon's horn; C, cortex; D, dentate gyrus; F, fimbria; H, hippocampus; P, choroid plexus; T, thalamus; V, lateral ventricle. ( $\times 68$ )

animals were allowed to survive for different periods after the injection and the utilization of the injected tritiated thymidine was examined by autoradiography. We found that numerous glia cells were labelled in brain regions structurally or functionally associated with the lesion site. This indicated induced proliferation of glia cells by the brain lesion. However, we found labelled glia nuclei in smaller numbers in areas which could not be related to the traumatized brain area, suggesting the possibility of glial multiplication as a normal phenomenon. In a subsequent study<sup>7</sup> we injected tritiated thymidine systemically into normal adult rats and intraventricularly into adult cats. The examination of this material showed that glia cells proliferate at a low but significant rate in virtually all parts of the normal, adult mammalian brain.

A more surprising finding was that not only the nuclei of glia cells but also the nuclei of occasional neurones were labelled in the brains of adult rats and cats<sup>8</sup>. We were particularly impressed by the labelling of granular nerve cells in the dentate gyrus of the hippocampus<sup>8</sup>. In all the animals (mature adults included) and all the sections examined a few labelled granule cells were always encountered. Since the granular layer of the dentate gyrus

is essentially devoid of the nuclei of glia cells, the labelling in this region could be attributed only to uptake of thymidine by the nuclei of the granule cells.

Accordingly, in our next investigation<sup>10</sup> we undertook to investigate in detail the nature and significance of DNA metabolism in the dentate gyrus of the hippocampus. Rats of varying ages (from neonates to adults) were injected systemically with tritiated thymidine and the animals were permitted to survive for selected periods after the injection. In addition, to obtain collateral material for histological evaluation the brains of a large series of non-injected rats of different ages were prepared for microscopy.

This study showed that the number of labelled cells in the dentate gyrus is very high in neonates and infants, and declines to a low but appreciable level in adults. Cell counting in collateral material showed that the number of differentiated granule cells in homologous sections increases six-fold from birth to 3 months of age, suggesting that the autoradiographic evidence may have reflected hippocampal neurogenesis. Counter-indicating this conclusion was the fact that mitotic cells were seldom encountered in the dentate gyrus. In further examination

Fig. 2 Percentage of labelled cells in the germinal lateral ventricle and in the dentate gyrus as a function of survival time after injection

of this material we were impressed by the fact that in the brains of neonate and infant rats there is an extensive ependymal and sub-ependymal germinal matrix around the lateral ventricle, composed of cells with darkly staining nuclei and occasional mitotic ones. Such darkly staining cells were also seen in the fimbria, and they were particularly numerous in the dentate gyrus in the brains of the younger animals. Quantitative work showed that the number of cells and the areal extent of the lateral

ventricle declined rapidly after birth, with a transient rise at about 15 days. A delayed, rapid rise could also be seen in the number of small cells in the dentate gyrus, showing a decline also at 15 days of age. The decline in the latter was accompanied by a corresponding increase in the number of differentiated granule cells with a peak at about 3 months of age. On the basis of these observations we postulated that undifferentiated cells or neuroblasts multiply at the lateral ventricle, migrate from there by way of the fibrous tracts of the hippocampus to the dentate gyrus and become differentiated there in the course of development into granule cells.

The hypothesis of the previous investigation was confirmed in an extensive subsequent series of experiments in which groups of neonate, infant, adolescent and adult rats were injected systemically with tritiated thymidine (10  $\mu$ c./g body-wt.; specific activity 6.7 c./mmole; radiochemical dissolved 1 mc./ml. in isotonic saline). The animals were allowed to survive for 6 h, 1, 3, 6, 12, (15), 20, 30, 60, 120 and 180 days after the injection. In this article we shall deal merely with some of the results obtained in the rats injected as neonates, particularly at 2 days of age. (A detailed evaluation of the entire experimental material is in preparation.)

In neonates injected with tritiated thymidine (Fig. 2) 35–40 per cent of the cells in the ependymal and sub-ependymal layers of the lateral ventricle were labelled in the animals killed 6 h after the injection. The rate of cell labelling, with concomitant dilution of labelling within cells, rose to about 60 per cent 24 h after the injection. With prolonged survival after injection there was a considerable dilution of the label within the cell nuclei and, after 6 days of survival, a reduction in the total number of labelled cells. This suggested a continued

Fig. 3. High-power photomicrograph of a galloyanin-chromalum-stained autoradiogram of granule nerve cells in the granular layer of the dentate gyrus. The animal was injected with tritiated thymidine at 2 days of age and survived for 20 days after the injection ( $\times 880$ )

multiplication of the initially labelled cells and their migration to other brain regions. Cell labelling was initially low in the dentate gyrus (less than 10 per cent), and in the animals with short survival after injection these were typically small cells with darkly staining nuclei, situated in the plexiform layers surrounding the ill-developed granular layer. The number of labelled cells increased to about 45-50 per cent by the 12th day after injection, by which time the majority of labelled cells have migrated into the thickening and expanding granular layer, and many of the labelled cells had the appearance of differentiated granule cells.

The distribution and differentiation of labelled cells in the granular layer followed a regular pattern. In animals killed 20 days after the injection, the top row of cells in the granular layer (the cells in intimate contact with the superficial plexiform layer) were typically unlabelled. These we consider the 'oldest' or earliest-differentiating cells of the dentate gyrus; derived from cells which multiplied before the administered thymidine became available. Below this row of unlabelled cells were many intensely labelled cells. Absence of appreciable label dilution indicated that these cells ceased to multiply soon after the injection; that is, they represent the 'oldest' of the post-natally formed cells. Moving from the superficial to the basal rows of granule cells intensity of cell labelling decreased gradually, with many unlabelled cells to be found in the basal rows of cells; the latter represent the 'youngest' of the granule cells. Cell size and cellular differentiation showed the reverse pattern. The cells in the superficial row tended to differentiate first and were among the largest; the basal cells were smaller and often undifferentiated.

The post-natal genesis of granule cells is not an exclusive characteristic of the dentate gyrus of the hippocampus. Our results show clearly that the bulk of the granule cells in the granular, mitral and glomerular cell layers of the olfactory bulb are formed post-natally. In this region neuroblasts proliferate at a high rate around the wall of the olfactory ventricle (Fig. 4), then move out and invade gradually the layers of the olfactory bulb, where they presumably differentiate. A large proportion of the granule cells of the internal granular layer of the cerebellar cortex (and to a lesser extent the Golgi cells and basket cells) are formed post-natally. This occurs both by local multiplication and through the migration of cells multiplying in the external granular layer (which is a germinal matrix that disappears in the rat at about 20 days of age)

Fig. 4. Percentage of labelled cells in the germinal olfactory ventricle and in the mitral and granular cell layers of the olfactory bulb in rats injected with tritiated thymidine at 3 days of age.

Fig. 5. Percentage of labelled cells in the external and internal granular layers of the cerebellum.

into the internal granular layer (Fig. 5). Similarly, the granule cells of the granular layer of the ventral cochlear nucleus are largely formed post-natally through migration of cells multiplying in the lateral recess of the fourth ventricle. It is very likely, though not conclusively proved, that many of the granular or stellate cells of the cerebral cortex also are of post-natal origin.

In the same structures in which a large proportion of the granule cells became labelled with tritiated thymidine, the nuclei of neighbouring large neurones remained typically unlabelled. The large mitral cells in the olfactory bulb were never seen with labelled nuclei, nor were the nuclei of the polymorph cells of the dentate gyrus, of the pyramidal cells of Ammon's horn, or the Purkinje cells of the cerebellum ever labelled. In general, large or long-axoned neurones (occasional ones in the cortex excepted) do not incorporate tritiated thymidine injected into neonates, whereas a considerable number of neuroblasts which afterwards differentiate into small, short-axoned neurones predictably utilize tritiated thymidine. From these findings we may conclude that there is a radical difference, from the developmental point of view, between the short-axoned neurones or microneurones<sup>11</sup> of the central nervous system and the long-axoned neurones or macroneurones. We shall not speculate here about the possible functional significance of the post-natal origin of the majority of microneurones. Elsewhere<sup>12</sup> we have made the suggestion that the pre-natally formed afferent, relay and efferent macroneurones represent the invariant or fixed components of the central nervous system, whereas the interposed microneurones, which develop post-natally as the animal comes to face and respond to its varied external environment, could be its modulatory and plastic elements.

## PROPRIOCEPTIVE INFLUENCE IN VOLITIONAL CONTROL OF INDIVIDUAL MOTOR UNITS

By DR. IRVING H. WAGMAN\* and DONALD S. PIERCE†

Biomechanics Laboratory and Department of Orthopaedic Surgery, University of California  
San Francisco Medical Center

AND

DR. RAY E. BURGER

Biomechanics Laboratory, University of California San Francisco Medical Center,  
and Department of Animal Physiology, University of California,  
Davis

HARRISON and Mortensen<sup>1,2</sup> recently showed that remarkably fine control over individual motor units was quickly established when auditory and visual cues to their activation were presented. Basmajian<sup>3</sup> confirmed these findings and also observed that such units could be recalled into activity without cues after training. He suggested that single anterior horn cells could be brought under conscious control by the training of descending pathways, and stated that the process by which such control is established may have a bearing on the general problem of learning.

These reports did not mention the possible role of the proprioceptive system, although it has long been recognized that such sensory information is essential for the co-ordination of motor performance<sup>4,5</sup>. It has also been shown<sup>6,7</sup> that the results of stimulation of the motor cortex of the cat can be influenced by changing the appropriate input from the responding limb.

In the course of our work with tungsten microelectrodes (ref. 8 and unpublished observations), we noted that proprioception was important in volitional activation of individual motor units. This consideration prompted us to re-examine the question of motor-unit control in the human in relation to knowledge of sensorimotor integration.

In the present investigation we used both our own type of microelectrodes and electrodes similar to those described by Basmajian. In 10 subjects, a number of different muscles were studied in minimal to moderate contraction, and the activity was recorded from one or two tungsten microelectrodes inserted into one muscle. A silver disk used as a reference electrode was placed on the skin over the tendon of the appropriate muscle. The electrodes were prepared from 10-mil straight tungsten wire by electrolytic etching until the tip was about 1  $\mu$  in diameter. The entire electrode except for the tip was insulated with either 'Formvar' or 'Epoxytite'. Before use, these electrodes, as well as the bipolar wire electrodes described below, were mounted in a special holder along with all accessory equipment and were sterilized in ethylene oxide.

The microelectrode was inserted into anaesthetized skin by placing it carefully either in a specially prepared inserter<sup>8</sup> or in a 22-gauge needle. After insertion in the muscle the carrier was gently withdrawn, leaving the electrode in place. Manipulation of the electrode was possible without bending or damage to the tip. The electrode was then connected to the recording apparatus by a fine wire lead soldered to a 1-cm length of 22-gauge

stainless steel tubing. With this type of electrode a unit was easily located when the muscle was minimally contracted.

The second type was a bipolar electrode made and inserted in a manner similar to that described by Basmajian<sup>3</sup>. Two 2-mil wires (either copper with 'Formvar' insulation or W. B. Driver Company's 'Evanohm' with nylon covering), the tips of which were bared of insulation for 1 mm, were inserted in a 22- or 24-gauge hypodermic needle so that their ends were bent back over the bevel of the needle about 4 mm from their tips. After insertion into the muscle (after sterilization) to an estimated appropriate depth, the needle was gently withdrawn, leaving the hooked wires in place. The separation of the tips of the wires was between 1.5 and 2.5 mm. The subject was rarely aware of any sensation attendant on the presence of these wires, even during fairly vigorous contraction of the muscle. This bipolar electrode was used to sample only minimal contractions in the abductor pollicis brevis, flexor pollicis brevis, and opponens pollicis in three experienced subjects (ourselves).

Both types of electrodes were connected to a remote cathode follower stage of a conventional *R-C* preamplifier. The output of the preamplifier was led into a cathode-ray oscilloscope and an audio system. The subject was comfortably seated facing the oscilloscope, so that he could both see and hear the activity. Even a naive subject quickly learned to identify single units and to distinguish one from others. We found, as did Harrison and Mortensen, that all subjects relied more on auditory than on visual cues.

In the course of the microelectrode experiments in the present investigation, it was found that factors other than auditory or visual cues played a part in the conscious activation of some individual motor units. Such units could often be followed with microelectrodes for as long as 15 min when the limb was held rigidly within a cast<sup>8</sup>. However, when no cast was worn individual units would often disappear when the subject changed his position slightly; there was generally no evidence in the traces that this could be due to damage to any unit caused by movement of the electrodes within the muscle. Occasionally, the same units would appear later if the electrode had not been moved. Little importance was attached to these observations until one subject pointed out that he could activate one specific gastrocnemius unit under study only if his ankle was maintained in plantar flexion. Fig. 1 is a recording from two such units in the gastrocnemius which showed a marked sensitivity to dorsiflexion of the ankle joint. The first part of both tracings shows the activation of these units under minimal contraction. However, when the foot was passively dorsiflexed only

\*Present address: National Primate Center and Department of Animal Physiology, University of California, Davis.

†Present address: Department of Orthopaedic Surgery, Massachusetts General Hospital, Fruit Street, Boston.

Fig. 1. Gastrocnemius unit activity recorded by means of two separate microelectrodes, each on a separate channel. In both A and B, the second pair of traces is continuous with the first pair. The indicated calibrations apply to both records. Slight baseline shifts are due to slight dorsiflexion and plantar flexion respectively. The unit shown in the top trace of A could be brought in by a minimal contraction. It could be activated at will, but only when the ankle joint was in plantar flexion. When the subject tried to reactivate the unit, he succeeded at his second attempt. The record illustrated in B was made about 5 min after that in A and with what the subject considered a slightly increased effort with the ankle joint in plantar flexion. Now at least two units are activated in the vicinity of the second electrode (bottom trace, B). One is activated along with the unit shown in the upper trace. The second is activated independently. The subject had been consciously attempting to bring in a unit during each of two different slight changes of position. When the foot was dorsiflexed  $3^\circ$  neither larger unit could be activated.

$3^\circ$  (as measured with a protractor) relative to the original position and held there and the gastrocnemius again contracted, these units were quiescent although the muscle was active. It was quickly established that in this and other subjects activation of these motor units depended on the resting length of the muscle, the position of the joint members in space, and the specific function that the muscle was called on to perform. Harrison and Mortensen made apparently somewhat similar observations, but did not point out the possible significance of these interactions since they only stated, in passing, that "slight changes in the position of the foot or leg were sometimes effective". From these experiments, which bring out the importance of the sensory system in the volitional activation of motor units, it was concluded that the neuromuscular system cannot be regarded as a simple hierarchy of motor units with thresholds of response graded according to the degree of contraction, as has often been suggested.

When these studies were extended to experiments with bipolar wire electrodes in the abductor pollicis brevis, it was found that because of the larger area of pick-up of the bipolar electrodes, a subject would invariably activate many units simultaneously when he contracted the muscle at the beginning of a session. In confirmation of Basmajian's report, it was found possible to gain control quickly over individual motor units singled out with the aid of auditory and visual cues. It was found even more clearly than in the experiments using microelectrodes that a unit that was singled out was highly dependent for its activation on the position of the thumb. In order to gain simultaneous control over more than one unit with the digit in the same position, an extended period of practice was essential. When such control was finally gained, the activation of each unit could be brought about without any detectable movement of the thumb, but the subject reported that the activation depended on recall of the original position and contraction effort necessary for activation.

Fig. 2 shows two units, each of which originally could be activated only when the thumb was in a markedly different position. After training, both units could be fired from one position; one unit could be stopped and the other activated discretely, within 100 msec; the necessary change in actual position of the thumb at this time was almost imperceptible, even to the subject.

The following additional observations were made in the course of these studies using minimal contractions. (1) When the thumb was immobilized by conscious effort with use of other muscles or by a cast, different units in the muscle under study could still be activated by alteration of contraction of the other muscles needed to stabilize the thumb. For example, different units in the abductor pollicis brevis could be activated by contraction of the opponens pollicis and/or the flexor digitorum longus. (2) The importance of peripheral input in establishing control over individual units was further emphasized by experiments in which the thumb and forearm were immobilized by a full forearm cast. The subject quickly learned to utilize the added sensation produced by pressure on the skin from the side of the cast as an aid in reproducing the state of muscle contraction under which the unit was originally singled out. (3) During any single training period, less and less effort from other muscles was necessary to activate specific units which were originally dependent in part on contraction of those other muscles. (4) As the ability of a subject to control motor units became progressively refined and accurate, he was able to activate certain higher-threshold units by using less tension than had originally been required to activate the lowest-threshold units.

Fig. 2. Recordings made from the abductor pollicis brevis with percutaneous electrodes (middle trace) and a fine bipolar electrode (bottom trace). These recordings were made after the subject had trained himself to select a unit with an almost imperceptible change in position of the thumb. At the signal, which the subject activated with his other hand, an attempt was made to stop one motor unit. The units are clearly recorded with the bipolar electrode, although even the percutaneous electrode shows evidence of them (especially the smaller unit seen in the bipolar recording). The jitters in the tracings indicate transient activation of other units in the muscle during the attempt to bring in the second unit. This is probably a more accurate indication of the time the subject began his attempt to bring in this unit than is the signal marker, which he rarely synchronized exactly with such an attempt.

It appears from these observations that, without training, volitional activation of descending pathways does not result in invariable responses of specific motor cells. Otherwise, the response of particular motor units would not be dependent on maintenance of certain positions of the limb or reproduction of a certain pattern of muscle contraction. During minimal or moderate contractions, the action of the descending pathways is modified, and perhaps controlled, probably in the anterior horn of the spinal cord, by peripheral input—proprioception, muscle contraction, or cutaneous stimuli. Appropriate sensory information, therefore, must be present for volitional activation of specific motor units. However, after an intensive period of training, precise conscious control over motor units can be established, with a lessened influence of peripheral stimuli.

# KINETICS OF ELIMINATION OF DRUGS POSSESSING HIGH AFFINITY FOR THE PLASMA PROTEINS

By DR. B. K. MARTIN

Nicholas Research Institute, Ltd., Slough, Buckinghamshire

THE classical method of determining the rate of elimination of a drug from the body is to examine the decline of the plasma concentration of the drug with respect to time. I have pointed out<sup>1</sup> that this method is only valid when throughout the period of investigation the plasma contains a constant proportion of the drug in the body and that this is not so when the drug is extensively bound to the plasma proteins. The application of the foregoing method to such drugs is therefore fundamentally unsound, and the values reported for the elimination rate or half-life of certain drugs, as determined from plasma data, may underestimate the rate of elimination. Certain factors operate which can cause the plot of log plasma drug concentration against time to be approximately linear and this has no doubt falsely encouraged belief in the validity of this method.

This article provides a theoretical consideration of the kinetics of elimination of a number of model drugs which have a high affinity for plasma proteins. A detailed analysis of the kinetics is complex, only a simple treatment is given here and the method of calculation cannot be regarded as mathematically exact.

In the previous work<sup>1</sup>, calculations were made relating to the distribution of a series of model drugs possessing different association constants ( $K_{sp}$ ) for a plasma protein, with the limitation that negligible binding of drug occurs in other tissues. Graphs were presented relating the amount of free drug in the body, and the amount of drug in plasma, to the total quantity of drug in the body. Using these data, the calculations are now extended to include the kinetics of elimination of these model drugs. For a given dose the amount of free drug in the body can be determined from the graph, and if an elimination rate constant applicable to the free drug is specified, the amount eliminated in 1 h can be calculated on the basis that the rate of elimination is proportional to the con-

centration of free drug. The amount eliminated is then subtracted from the original total to obtain the amount of total drug remaining and the amount of free drug again determined graphically; this process is repeated for each hour to construct the pattern of elimination over several hours. The corresponding amount of drug in the plasma at each stage of the elimination process is determined from the appropriate graph. Data relating to total drug decline, plasma drug decline and urinary excretion rate from two such calculations are plotted in Figs. 1a and b.

If  $D_f$  = concentration of free (non-bound) drug in body water,  $D_b$  = concentration of bound drug in plasma,  $V_p$  = plasma volume,  $V_t$  = volume of total body water, then: total drug in body ( $D$ ) =  $D_f V_t + D_b V_p$ ; free drug in body ( $D_f$ ) =  $D_f V_t$ ; bound drug in body ( $D_b$ ) =  $D_b V_p$ ; total drug in plasma ( $D_p$ ) = ( $D_f + D_b$ )  $V_p$ .

The model system may be represented as:

where  $D_e$  is the amount of drug eliminated.

In the process of drug elimination, the decline in  $D_f$  is the net effect of loss of free drug by elimination and of gain of free drug arising from the dissociation of  $D_b$ .

$$-\frac{dD_f}{dt} = -\frac{dD}{dt} + \frac{dD_b}{dt} \quad (1)$$

If the loss of drug by elimination is proportional to  $D_f$ , then:

$$-\frac{dD}{dt} = K_f D_f \quad (2)$$

where  $K_f$  is a first-order elimination rate constant applicable to the amount of free drug in the body.  $D_f$  is not a

Fig. 1 Plots of the log drug in the body (m.moles), log drug in plasma (m.moles), and log rate of elimination (m.moles/h) against time for two model drugs of  $K_{sp} = 1 \times 10^3$  (Fig. 1a) and  $1 \times 10^4$  (Fig. 1b) undergoing elimination at a rate of 20 per cent/h of the amount of free (non-bound) drug. Initial drug present 6 m.moles. Data calculated for a 70-kg man on the basis previously described<sup>1</sup> ( $P = 5 \times 10^{-4}$  M,  $\alpha = 1$ ,  $V_p = 3$  l.,  $V_t = 42$  l.)

constant fraction of  $D$ ,  $(D_F/D)$  diminishes and elimination becomes relatively slower as it proceeds. Neither the decline of drug nor the decline in the rate of elimination is first order.

In respect of the decline of drug in plasma, the decrease in  $(D_F/D)$  as elimination proceeds is partly compensated by the increase in  $(D_F/D)$ , and the rate of decline of drug in plasma consequently underestimates the rate of drug elimination. This is particularly marked at high dosage. The variation of  $(D_F/D)$  and  $(D_P/D)$  for the model drug of  $K_{ep} = 1 \times 10^3$  is such that the plot of  $\log D_P$  against  $t$  is curved, but closely approximates to two linear sections of different slope, at first showing a gentle decline and then a steeper decline (Fig. 1a). The decline in  $\log$  plasma drug concentration not only underestimates the rate of drug decline at high levels but later also gives the false impression that the  $\log$  rate of elimination has increased, whereas elimination becomes relatively slower, rather than faster, at low drug concentrations.

These calculations relate to model drugs which exhibit no appreciable binding in other tissues. Several drugs will consequently show departures from this idealized behaviour, but probably in no instance can the rate of decline of high plasma drug concentrations be accepted as a valid indication of the rate of drug decline.

An increase in slope of the  $\log$  plasma drug concentration as elimination proceeds has been reported for procaine<sup>2</sup>, streptomycin<sup>3</sup>, dicoumarol<sup>4</sup>, ethyl bisacoumate<sup>5</sup> and phenylbutazone<sup>6</sup>, all of which are bound to the plasma proteins. This has been interpreted in terms of relatively slower elimination at higher doses. This may well be so—it is with salicylic acid<sup>7</sup>—but in the absence of additional evidence, the present considerations indicate that such a deduction is not justified and that the change in slope of the  $\log$  plasma drug decline can arise simply as a consequence of the interaction of the drug with plasma proteins.

The rate of decline of drug in the body can be assessed from urinary excretion data by constructing the pattern of decline of that fraction of the dose which is excreted unchanged, that is, by a plot of  $\log (D_{U\infty} - D_{Ut})$  against  $t$ , where  $D_{U\infty}$  is the amount of unchanged drug ultimately recovered in the urine, and  $D_{Ut}$  is the cumulative amount recovered to time  $t$ . The interpretation of data, which includes the excretion of drug metabolites, is complicated by the process of metabolite accrual<sup>8</sup>.

It is frequently asked, what is the effect of protein-binding on the rate of drug elimination? It has been suggested<sup>1</sup> that this depends not only on certain factors

which remain constant, but also on the amount of drug present in the body, and the magnitude of the effect will increase as elimination proceeds. There is therefore no simple answer, although the maximum potential effect can be stated. Alternatively, what would be the elimination rate constant of the drug if it exhibited no interaction with plasma protein? This theoretical concept has been introduced and the relevant rate constant ( $K_F$ ) is identified in equation (2). For certain drugs it may prove possible to estimate  $K_F$  directly from urinary excretion data only. If a drug has a high  $K_{ep}$  and its therapeutic dose is such that after one or more doses the plasma protein closely approaches saturation with drug, then limited elimination of drug can take place without appreciable change in  $D_B$ . If  $D_B \rightarrow$  constant,  $dD_B/dt \rightarrow 0$ , then from equations (1) and (2):

$$-\frac{dD_F}{dt} = -\frac{dD}{dt} = K_F D_F = K_F D_{Fe} - K_F t$$

hence:

$$\ln \left( -\frac{dD}{dt} \right) = \ln D_F K_F - K_F t \quad (3)$$

In terms of urinary excretion data<sup>9</sup>:

$$\ln \left( -\frac{dD_U}{dt} \right) = -K_F t + \text{constant} \quad (4)$$

A plot of the  $\log$  amount of unchanged drug excreted in a series of equal intervals of time ( $dD_U/dt$ ) is almost linear over this limited period and  $K_F$  can be assessed from its slope (Fig. 1a). This plot afterwards becomes distinctly curved and it is also at this time that the  $\log$  drug plasma plot exhibits a marked change in slope.

Two well-known methods for the treatment of urinary excretion data have been utilized in this work. In this instance they yield entirely different information,  $(D_{U\infty} - D_{Ut})$  is used to assess the decline of total drug, while  $(dD_U/dt)$  is proportional to the amount of free drug.

## LIGHT-INDUCED STOMATAL OPENING AND THE POSTULATED ROLE OF GLYCOLLIC ACID

By PROF. O. V. S. HEATH, F.R.S., DR T. A. MANSFIELD\* and DR HANS MEIDNER

University of Reading Horticultural Research Laboratories, Shinfield, Berkshire

THE history of investigation of the physiology of stomata has been one of successive hypotheses, usually based on one aspect only of the evidence, each attempting to explain in terms of a single relatively simple mechanism the way in which changes in environmental factors affect guard cell turgor and produce stomatal movement. Francis Darwin<sup>1</sup> himself accumulated enough experimental evidence of the complexity of stomatal behaviour in response to various stimuli to show that no very simple single explanation of the stomatal mechanism was to be expected, and of recent years this has been made even more apparent by the results of much experimentation under more rigidly controlled conditions. A new hypothesis, largely based

on observed effects of metabolic inhibitors on stomatal aperture, has now suggested that the photosynthetic production of glycollic acid plays a major part in the stomatal mechanism<sup>2-4</sup>.

In this article we discuss the complexity of the effect of light on stomatal movements, including some new findings concerning an effect of blue light which is apparently independent of carbon dioxide, and show, with some experimental evidence relating to the effects of metabolic inhibitors, the inadequate nature of the new hypothesis.

Metabolic inhibitors have proved most valuable in plant physiology when used in conjunction with measurements of the rate of a metabolic process, notably respiration, or photosynthesis as carried out by isolated chloroplasts or

\* Present address: Department of Biology, University of Lancaster.

even unicellular algae. When the process measured is the resultant of a large number of simultaneous complex biochemical and physical processes, an exclusive reliance on metabolic inhibitors can sometimes result in "confusion worse confounded", for so-called specific inhibitors are seldom as specific as their users would like to think. The number of compounds which will, for example, inhibit growth of coleoptile sections, even when in low concentration, is legion. The finding that a 'specific' inhibitor for a particular enzyme will prevent or reduce growth does not necessarily show that the mechanism of growth is entirely, or even mainly, explicable in terms of that enzyme system.

A somewhat similar situation holds for stomatal movements. There is evidence, referred to here, that at least three light-operated mechanisms are involved in stomatal opening, one acting through the carbon dioxide concentration in stomatal guard cells, the second causing stomatal opening independently of carbon dioxide and the third controlling the phase of endogenous rhythms.

The first-mentioned mechanism is controlled partly by photosynthesis in the guard cells themselves<sup>6</sup> and partly by that in the mesophyll<sup>6,7</sup>. The photosynthetic production of osmotically active substances in the guard cells may be expected to assist opening but is of minor importance compared with the effect of photosynthesis in reducing the carbon dioxide concentration; this is shown by the facts that in light, increasing the ambient carbon dioxide concentration does not cause opening but partial closure<sup>8,9</sup> and that wide stomatal opening can be brought about in the dark by exposing leaves to air free of carbon dioxide<sup>6</sup>. The hydrolysis of guard cell starch is much affected by carbon dioxide concentration, but not by light *per se*<sup>6</sup>, with the possible exception of blue light.

Secondly, stomatal opening due to an effect of light on the guard cells operating independently of carbon dioxide concentration was postulated by Heath and Russell<sup>4</sup>, who found stomatal responses in wheat to changes in light intensity while the intercellular carbon dioxide concentration was kept between zero and 0.01 per cent; in that range, wheat stomata were found not to respond appreciably to changes in the carbon dioxide concentration<sup>4,5</sup>. The results of Mouravieff<sup>10</sup> later implied that if there was a carbon dioxide-independent effect of light on stomatal guard cells, this effect was probably due to short wave-lengths in the blue region. Recently we have tested stomatal responses to blue and red light, and have confirmed that in blue light stomata open further than in red light even when the intercellular space carbon dioxide concentration in blue light is higher than in red. Leaves of *Xanthium pennsylvanicum* Wall. were illuminated in a closed system and allowed to establish  $\Gamma$ , the minimum intercellular space carbon dioxide concentration<sup>11</sup>. When red or blue light (from broad-band sources, practically free of far- and infra-red) was applied so that the incident quantum supply was approximately the same in each wave band, namely, 3,400 ergs/cm<sup>2</sup>/sec of red and 4,550 ergs/cm<sup>2</sup>/sec of blue,  $\Gamma$  remained more or less constant at 127 p.p.m. of carbon dioxide (average for 8 leaves). However, in red light log stomatal resistances (measured in log Gregory and Pearse units)<sup>12</sup> were on average 1.22 whereas in blue light they were 1.34 for the same leaf area. In another experiment we have shown that with blue light at lower intensities than red, the former can still produce wider stomatal opening, in spite of a larger  $\Gamma$ -value, that is with a higher carbon dioxide concentration within and surrounding the leaf. In these experiments light-induced stomatal opening from darkness occurred with an output of carbon dioxide from the leaf into initially carbon dioxide-free air. Thus there could have been no net gain of photosynthate and the postulated production of new carbohydrate<sup>6</sup>, whether via glycolic acid or by any other path, could not have occurred. These findings will be reported more fully elsewhere.

Thirdly, the light effect controlling the phase of the rhythm which proceeds in darkness has been shown elsewhere<sup>13</sup> to be brought about by wave-lengths in the neighbourhood of 700 m $\mu$ . This light effect is distinguished from those more directly concerned with stomatal opening both by the action spectrum and the fact that the intensity required to elicit a phase shift ( $< 100$  ergs/cm<sup>2</sup>/sec) is well below that required for the production of detectable opening. The endogenous rhythm in darkness can considerably modify the re-opening in high-intensity light<sup>14</sup>, and consequently the light reaction which affects the phase of this rhythm may make a significant contribution to regulation of the opening response to light.

The foregoing complexities have been listed with reference to effects on guard cells alone, but it was first postulated by von Mohl<sup>15</sup> and demonstrated experimentally by Heath<sup>16</sup> that the degree of stomatal opening depends on the turgor difference between the guard cells and the neighbouring epidermal or subsidiary cells. A further physical complexity is added by the different types of thickening of the guard cell walls so extensively studied by Schwendener<sup>17</sup>.

With such a system it is naive to look for a single all-embracing explanation of stomatal movement, or even of stomatal responses to light. It is not surprising that a great many chemical agents damage one component or another sufficiently to cause stomatal closure or prevent opening. A great deal of early work showed that bathing isolated epidermis, portions of leaf or intact leaves with various buffer solutions at the same or different pH values, or various acids, alkalis and neutral salt solutions had complex effects on stomatal aperture and stomatal starch content<sup>18</sup>. More recently, Zelitch<sup>3</sup> listed eighteen compounds (mainly inhibitors, plant growth substances or chelating agents) which partially or completely prevented opening of the stomata on tobacco leaf disks floated on solutions of  $10^{-3}$  M or lower concentration (this list included glycolic acid—see below). In a later paper<sup>3</sup> he listed a further thirteen compounds which partially prevented opening in concentrations between  $5 \times 10^{-3}$  M and  $3 \times 10^{-2}$  M and truly remarked "the wide range of compounds that influence stomatal movements suggests that there are many sites at which the opening of stomata may be interfered with to cause closing". Since the relaxed position of the guard cells results in stomatal closure, substances causing opening are more unusual and likely to be of more potential interest, though here also there is a danger of misinterpretation as toxic effects may act differentially on the neighbouring epidermal cells which are in general more easily damaged than the guard cells; loss of turgor by the epidermal cells tends to cause stomatal opening. This danger has been avoided by Mouravieff<sup>10</sup>, who works mainly with isolated stomata.

Zelitch<sup>3</sup> has produced a scheme, based mainly on the results of studies with inhibitors, to account for both light-induced stomatal opening and carbon dioxide-induced stomatal closure. It is assumed that in the main light-induced stomatal opening is due to the photosynthetic formation in the guard cells of glycolic acid and its further metabolism to glyoxylic acid and thence to carbohydrate, resulting in an increase of osmotic pressure. The inhibitors used in the investigations leading to the formulation of this scheme were  $\alpha$ -hydroxysulphonates, and their action has been explained in terms of their effect on glycolic acid oxidase, so that it is not here the synthesis of glycolic acid but its further metabolism which is affected<sup>19</sup>. Glycolic acid is said to accumulate rapidly in the leaf if these inhibitors are present; within thirty minutes it may accumulate twenty-fold<sup>19</sup>. The closing effect of high carbon dioxide concentration, on the other hand, is supposedly due to inhibition of photosynthetic formation of glycolate<sup>3</sup>.

Zelitch has also speculated that stomatal opening may require adenosine triphosphate produced by photosynthetic phosphorylation and that a glycolic acid—

Fig. 1. Stomata on a detached leaf of *Xanthium pennsylvanicum*, in the course of opening in light of 8,000 lux, begin to close when  $10^{-3}$  M  $\alpha$ -hydroxy-2-pyridinemethanesulphonic acid is fed through the petiole (time of application indicated by arrow). Flushing the leaf with air free of carbon dioxide completely reverses the effect of the inhibitor, application of which was continued through the rest of the experiment. During the carbon dioxide-free air treatment a continuous record was obtained. Ordinate indicates degree of opening on the scale of the recording resistance porometer of Heath and Mansfield<sup>10</sup>.

glyoxylic acid shuttle may be involved. (We have discussed this elsewhere<sup>22</sup>, but it is not incorporated in his main scheme<sup>23</sup>.)

We have recently studied the effects of  $\alpha$ -hydroxy-sulphonate inhibitors on stomatal behaviour in *Xanthium pennsylvanicum*. Although our results fully confirm that these substances cause stomatal closure, we have also observed that the closing effects can be quickly and completely reversed by flushing the leaf with air free of carbon dioxide. A typical result from a series of experiments is shown in Fig. 1. This observation is open to two possible explanations, neither of which appears compatible with the glycollic hypothesis proposed<sup>1-4</sup>. One possibility is that it is the glycollic acid itself accumulating in the tissue (due to inhibition of its subsequent metabolism) that causes the closure. Flushing the leaf with air free of carbon dioxide would reduce photosynthetic production to a minimum and stop further accumulation of the acid. That already accumulated might then be removed if glycollic acid oxidase were not completely blocked. Zelitch's own observations (ref. 2, Table 2) have shown that glycollic acid at a concentration of  $10^{-3}$  M causes 26-50 per cent stomatal closure. However, results of recent experiments, to be published elsewhere, have shown that glycolate accumulation *per se* causes neither stomatal closure nor reduction in photosynthetic rate. The most likely possibility is that the inhibitor reduces photosynthetic rate, resulting in an increase in the intercellular space carbon dioxide concentration and thereby inducing stomatal closure. Asada and Kasai<sup>21</sup> have shown in barley, tobacco and *Chlorella* that  $10^{-3}$  M  $\alpha$ -hydroxysulphonate severely affects the rate of photosynthetic carbon dioxide uptake. Zelitch<sup>22</sup> considers that it is stomatal closure that causes reduced photosynthetic rate, but in view of the fact that photosynthesis in *Chlorella* was similarly affected this is most unlikely. The simplest explanation of our observation (Fig. 1) is that flushing the intercellular spaces with air free of carbon dioxide removes the respiratory carbon dioxide which is accumulating due to a reduction in photosynthetic rate. The normal sensitivity of the stomata to carbon dioxide does not appear to be affected by the inhibitor.

Zelitch<sup>2</sup> has proposed that stomatal closure in high carbon dioxide concentrations is caused by the inhibition of carbohydrate formation via the glycolate pathway. One would expect more carbohydrate to be formed at such concentrations, even if not by that pathway, but the observed effects of carbon dioxide on stomatal movement do not in any event support the hypothesis. Pritchard, Griffin and Whittingham<sup>23</sup> have shown for *Chlorella* that glycolate excretion into the medium is maximal with 0.1 per cent carbon dioxide in the gas phase and decreases both above and below this concentration.

At zero carbon dioxide concentration there can be little, if any, photosynthetic formation of glycolate, and on Zelitch's hypothesis illuminated stomata should therefore show closure in carbon dioxide-free air; they should open to a maximum value as the carbon dioxide concentration is increased and then close again at still higher concentrations. In fact stomatal aperture is maximal in carbon dioxide-free air, shows no detectable change with the first small increase of concentration (to about 0.01 per cent for wheat<sup>24</sup>) and then decreases to approach a steady value at a concentration which depends on the light intensity, but up to 800 ft.-candles is in the range of physiologically high concentrations from 0.05 to 0.08 per cent<sup>25</sup>. Concentrations of 1.8 or 0.5 per cent, as used by Zelitch, are far outside the physiological range. There thus appears no better evidence that reduction in the rate of glycolate synthesis accounts for the closing responses of stomata to carbon dioxide than there is that the further metabolism of glycollic acid to carbohydrate accounts for their opening response to light.

**Opening due to removal of carbon dioxide.** All wavelengths of light in which photosynthetic uptake of carbon dioxide occurs will produce opening. This effect can be simulated in darkness by flushing the leaf with air free of carbon dioxide<sup>24</sup> and it may, therefore, be said to be non-photosynthetic since it does not necessarily depend either on light or on carbon dioxide fixation; the role of photosynthesis is an indirect one.

**Opening component independent of carbon dioxide.** We have shown above that this is brought about by blue light. The opening occurred in a system in which there could be no net photosynthetic carbon dioxide uptake.

**Low-intensity light effect.** Light of very low intensity (most effective at 700 m $\mu$  wave-length) can alter the phase of a rhythm of 'opening ability' proceeding in darkness and so control the rate of light-induced opening in high light intensity.

**Mechanisms of light effects.** It seems most improbable that there is much in common between the unknown mechanisms by which the foregoing three light effects control guard cell turgor and hence stomatal opening.

**Role of glycollic acid.** Stomatal opening occurred in either red or blue light with no net carbon dioxide fixation and hence no production of osmotically active photosynthates via glycolate or by any other path. Appreciable formation of glycolate is not therefore essential for light-induced opening.

## ASTROPHYSICS

## A Sensitive Test for the Presence of Atomic Hydrogen in Intergalactic Space

FIELD<sup>1</sup> has stressed the importance of the scattering of Lyman- $\alpha$  quanta on hydrogen atoms in determining the spin temperature of intergalactic hydrogen. The purpose of this communication is to point out that the scattering itself provides an extraordinarily sensitive indication of the presence of atomic hydrogen.

According to Field<sup>1</sup> (equation 11) radiation emitted at wave-lengths shorter than Lyman- $\alpha$  is scattered:

$$N = 2.4 \times 10^{14} n_H$$

times while it is red-shifted through the Lyman- $\alpha$  line. (Field assumed that Hubble's constant is 180 km/sec Mpc, but the order of magnitude of  $N$  should be correct in any case.) Thus, with a typical 'cosmological' density of  $n_H = 10^{-5}$  atoms  $\text{cm}^{-3}$ , a quantum emitted with a wave-length shorter than Lyman- $\alpha$  is scattered  $10^4$  times, and has a negligible chance of continuing in its initial direction. Even a density of  $10^{-6}$  atoms  $\text{cm}^{-3}$  would very effectively scatter such radiation. Thus, if any radiation is observed from a discrete extragalactic source in the range of wave-lengths between the local and the red-shifted Lyman- $\alpha$  wave-lengths, the density of hydrogen atoms in intergalactic space is  $< 10^{-6} \text{ cm}^{-3}$ .

Ultra-violet spectroscopy by rocket or satellite-borne telescopes cannot, as yet, reach the galaxies one would wish to examine. However, Schmidt<sup>2</sup> has shown that the optical object associated with the radio source 3C 9 has a red-shift  $z = 2.012$ , and its Lyman- $\alpha$  emission line is red-shifted into the visible spectrum. Schmidt's paper is concerned only with the two emission lines of 3C 9, and there is no explicit mention of a continuum. The Lyman- $\alpha$  line is some tens of Å units wide, and the fact that the centre of the line is not noticeably displaced might already be considered as evidence that there is no noticeable scattering within the first Mpc around 3C 9. However, it is quite possible that 3C 9 has a peculiar velocity of a few 100 km/sec, and it is also possible that intergalactic hydrogen in the vicinity of 3C 9 is exceptionally highly ionized. Thus a decision must await a new examination of Schmidt's spectrum.

If the scattering were appreciable, then the radiation emitted at a particular frequency would be scattered from a spherical shell around the source, the radius of which is proportional to the difference between the emitted wave-length and Lyman- $\alpha$ . Observation of such scattered light would, in principle, yield Hubble's 'constant' as a function of  $z$ , and hence provide a history of the expansion of space. Unfortunately, the detection of such faint radiation distributed over disks many minutes of arc in diameter is beyond the reach of observation.

If it turns out that 3C 9 has a continuum below 3660 Å, then either the mean density of hydrogen is exceedingly low, or its ionization is very complete. The conditions required to produce such complete ionization will be examined elsewhere. A third possibility, that the red-shift of 3C 9 is not cosmological<sup>3</sup>, cannot be ruled out at present.

*Note added in proof.* I understand from Dr. Schmidt that work on the lines suggested in the foregoing letter

has been carried out independently by Gunn and Peterson (*Astrophys. J.*, in the press).

## RADIOPHYSICS

## Ordinary Mode Whistlers observed In Satellites

SMITH *et al.*<sup>1</sup> recently published dynamic spectra of a very interesting phenomenon observed in the satellites *Alouette I* and *Injun III*. One of these is reprinted here as Fig. 1A. This shows a whistler (rapidly falling part) produced by (extraordinary mode) dispersion of an atmospheric propagated upwards to the satellite. The whistler is followed by a rising trace which flattens out at a frequency which could correspond to the ion gyro-frequency.

Although such a sequence of events may suggest a 'triggering' process for the rising trace<sup>2</sup>, I would like to show that the spectral (frequency-time) shapes of both traces can be closely matched if both are interpreted as dispersed forms ('whistlers') of the original atmospheric. Thus the falling trace is an extraordinary mode whistler and the rising part an ordinary mode whistler.

The ordinary mode can propagate only below the ion (proton) gyrofrequency. For frequencies very much less than the electron gyrofrequency, the refractive indices (for longitudinal propagation) become<sup>3</sup>:

$$n^2 = a(g \pm f)^{-1}$$

where  $g$  is the proton gyrofrequency,  $f$  the wave frequency, and  $a$  the scale frequency (ratio of plasma frequency squared to the gyrofrequency, for either protons or electrons). The plus and minus signs correspond to the extraordinary and ordinary modes respectively ( $f < g$  for the latter). I have assumed a neutral plasma of electrons and protons only. The group refractive indices are then (signs as above):

$$n_g = a^{1/2}(g \pm \frac{1}{2}f)(g \pm f)^{-3/2}$$

The travel times of waves in the two modes can be calculated from this with an appropriate model. Fig. 1B shows the result of such a calculation using parameters ( $a, g$  and path length) to fit the observed dynamic spectrum in Fig. 1A.

The agreement for both modes is quite reasonable. Effectively only two independent parameters can be chosen to obtain a fit. These determine the time and frequency scale. The shape is mainly determined by the refractive index expression given here and only slightly by the model or form of the plasma density and magnetic field variation. The effects of other ions do not appear to be important.

Jacobs and Watanabe<sup>3</sup> have suggested that certain types of micropulsations which have dynamic spectral shapes like the rising part shown in Fig. 1A might be such ordinary mode whistlers (they used the term

Fig. 1. A, Event observed by *Injun III* (after Smith *et al.*<sup>1</sup>). B, An attempt to match the event shown in A by the two-mode whistler hypothesis. The solid curves correspond to the portions actually observed. The time of the initiating atmosphere is shown by the vertical broken line.

'micropulsation whistlers'). This adds considerable weight to their theory and is perhaps the first direct evidence that these can be initiated by an atmospheric impulse.

*Note added in proof.* Since this letter was submitted the same idea has been presented by Gurnett *et al.*<sup>4</sup>

### The Appleton Anomaly

In recent communications<sup>1,2</sup> and an earlier letter<sup>3</sup> various workers have shown that electrodynamic drift (that is, magnetohydrodynamic motion of the magnetic field lines) in the *F2* layer would give rise to a phenomenon

similar to the observed Appleton anomaly. However<sup>1,2</sup>, the required drift speeds are much smaller than the 20 m/sec or more predicted by dynamo theory<sup>4,5</sup>.

Meanwhile, work in progress elsewhere<sup>6-8</sup> has suggested that the topside *F2* layer is in diffusive or hydrostatic equilibrium. In fact, when the possible effects of electrodynamic drift are considered above the peak<sup>9,10</sup>, it is found that even drifts of the order of 10 m/sec should have very large effects indeed.

In view of this apparent discrepancy between what the drift should be, and what it actually is, we have investigated a possible explanation in terms of horizontal motion of the neutral air caused by ion drag. Earlier workers<sup>11-13</sup> have previously discussed the effects of such motion at moderate latitudes, and have shown that the apparent vertical electrodynamic drift is reduced by such motion, and the apparent horizontal drift is increased. In the case when the horizontal motion of the neutral air exactly matches the horizontal velocity of the ions we find<sup>14</sup> that in the absence of electrodynamic drift there is a deep equatorial trough in  $N_m$  of about the same depth as the trough in the observed Appleton anomaly. However, the latitudinal maxima of  $N_m$  occur at the approximate latitudes of 10°.

In the case of perfectly matched horizontal velocities, the apparent vertical drift is cancelled, and the horizontal drift is enhanced. It seems clear, therefore, that this horizontal drift, when included, would move the maxima outward to latitudes of  $15^\circ$ , as in the actual anomaly. Although we have not considered the dynamics of such horizontal circulation, other workers<sup>18</sup> have discussed the principal operative forces.

In view of this, it seems a reasonable conjecture that the complete description of the equatorial  $F_2$  layer may lie somewhere between these extremes. Account may have to be taken of production<sup>16</sup>, loss<sup>17</sup>, diffusion<sup>18,19</sup>, electrodynamic drift<sup>20</sup>, horizontal air motions<sup>21</sup> and temperature variations<sup>21</sup> (see also ref. 22) in assessing quantitatively the grosser features of the  $F_2$  layer at low latitudes.

Other possibilities include electric currents along the magnetic field lines between conjugate points of the dynamo region<sup>22</sup>, and electric field effects associated with the necessity for the electric field to be irrotational<sup>24</sup>. However, the possible importance of these further effects has not yet been investigated.

## PHYSICS

### Lorenz Number of Plutonium Metal

RECENT work on the thermal conductivity ( $k$ ) and electrical conductivity ( $\sigma$ ) of pure  $\alpha$ -phase plutonium revives the question of the magnitude of the Lorenz number  $L (= k/\sigma T)$ .

The early work of Sandenaw and Gibney<sup>1</sup> gave  $L$  at  $20^\circ\text{C}$  between  $3.96$  and  $4.41 \times 10^{-8}\text{ V}^2\text{ deg}^{-2}$ , very much in excess of the theoretically expected value ( $2.45 \times 10^{-8}\text{ V}^2\text{ deg}^{-2}$  at a temperature above the Debye temperature, the latter being  $192^\circ\text{K}$  for plutonium). It is unlikely that the difference could be wholly accounted for by a lattice contribution to the thermal conductivity. However, their thermal conductivity value ( $0.020\text{ cal cm}^{-1}\text{ sec}^{-1}\text{ }^\circ\text{C}^{-1}$ ) was not confirmed by the later work of either Lee and Mardon<sup>2</sup> ( $k$  between  $0.008$  and  $0.010\text{ cal cm}^{-1}\text{ sec}^{-1}\text{ }^\circ\text{C}^{-1}$ ) or myself<sup>3</sup> ( $k = 0.0098\text{ cal cm}^{-1}\text{ sec}^{-1}\text{ }^\circ\text{C}^{-1}$ ). These lower values have now been confirmed by

a measurement of the room-temperature thermal diffusivity<sup>4</sup> as  $0.02\text{ cm sec}^{-2}$  which, using the specific heat data of Kay and Loesby<sup>5</sup> ( $0.034\text{ cal g}^{-1}\text{ }^\circ\text{C}^{-1}$ ) and a density of  $19.6\text{ g cm}^{-3}$ , gives a thermal conductivity of  $0.013\text{ cal cm}^{-1}\text{ sec}^{-1}\text{ }^\circ\text{C}^{-1}$ . The problem now arises that using these lower values of  $0.01$  for  $k$  and  $142 \times 10^{-8}\text{ ohm-cm}$  as the room-temperature electrical resistivity<sup>6</sup>,  $L$  is reduced to about  $2.0\text{ V}^2\text{ deg}^{-2}$ , nearly 20 per cent lower than the theoretical value and clearly not to be explained by the presence of any additional conduction mechanism.

Linde<sup>7</sup> seems to have been the first to point out the low values of  $L$  given by a number of pure metals and suggested that an additional term should be included by splitting the total thermal resistance of a metal into two components, one determined by impurities and lattice defects and hence independent of temperature, the other determined by lattice vibrations. This is an obvious thermal analogy to Matthiessen's rule for electrical resistivity. Linde's theory was extended by Bäcklund<sup>8</sup>, who removed Linde's restriction that the resistivity temperature curve had to be linear and suggested the amended form of the Weidemann-Franz law:

$$\frac{k(\rho + \bar{\rho}_0)}{T} = L$$

where  $\rho$  is the electrical resistivity and  $\bar{\rho}_0$  the intercept obtained by extrapolating back the linear low temperature part of the resistivity-temperature curve to zero temperature. Applying this to the foregoing values of  $k$  and the recent resistivity data of Meeden<sup>9</sup>, a value of  $2.48 \times 10^{-8}\text{ V}^2\text{ deg}^{-2}$  is obtained for  $L$ . This close agreement with the theoretical Lorenz number would appear to be a vindication of the Bäcklund theory. However, recent papers by King *et al.*<sup>10</sup> and Wigley<sup>11</sup> show that Matthiessen's rule fails completely for plutonium at low temperature due to the additional temperature-dependent resistivity caused by self-irradiation. It remains to be shown whether the thermal resistivity is similarly affected by self-irradiation. A theoretical justification for the applicability of an argument similar to Bäcklund's for the various electron scattering mechanisms awaits a fuller understanding of a peculiar behaviour of the electrical resistivity of plutonium<sup>11</sup>.

The value of  $\bar{\rho}_0$  for uranium from Meeden's results<sup>9</sup> amounts to only 3 per cent of the room temperature resistivity, a variation insignificant compared with the range of values of  $L$  consequent on the various available experimental values of  $k$ .

### Infra-red Evidence of the Grinding Effect on Hydrargillite Single Crystals

SEVERAL investigations of the infra-red spectrum of hydrargillite powder have been reported<sup>1-4</sup>. However, no study of single crystals as yet seems to have been reported. In the present investigation, thin plates were cut from a single crystal of synthetic hydrargillite (product of Showa Denko Co.) about  $3\mu$  thick, some parallel to the (001) plane and some nearly perpendicular to the (001) plane. The absorption spectra were recorded in the region of  $4,000\sim 450\text{ cm}^{-1}$ . The spectra so obtained were

Fig. 1. Infra-red spectra of synthetic hydrargillite: A,  $\nu$ OH region; B,  $\delta$ OH region. Curve 1, single crystal, the incident beam is nearly parallel to (001) plane; curve 2, single crystal, the incident beam is perpendicular to (001) plane; curve 3, powder obtained by grinding the single crystal (nujol).

compared with the powder spectra and several points of difference were found.

According to the literature<sup>1-3</sup>, the spectrum of hydrargillite powder has characteristic OH bands at the following wave numbers: 3,617 (or 3,620), 3,520, 3,428 and 3,380 for  $\nu$ OH, and 1,060 (occasionally present)<sup>4</sup>, 1,020, 969, 914 and 560 for  $\delta$ OH (the 560  $\text{cm}^{-1}$  band can reasonably be assigned to  $\delta$ OH with the deuteration data by Kolesova<sup>5</sup>, though no report has appeared on the assignment).

The powdered sample in the present investigations was obtained by grinding the crystal, and gave characteristic OH absorption bands at the following wave numbers:

3,617, 3,520, 3,460, 3,420 and 3,380 for  $\nu$ OH (Fig. 1A, curve 3), and 1,020, 969, 914 and 560 for  $\delta$ OH (Fig. 1B, curve 3). The strong 3,460  $\text{cm}^{-1}$  band is believed to correspond to the 3,428  $\text{cm}^{-1}$  band reported in the literature due to the similarity of shape and intensity.

The OH absorption bands of the single crystal were found at the following wave numbers: 3,617, 3,520, 3,420, 3,400 and 3,380 for  $\nu$ OH (Fig. 1A, curves 1 and 2), and 1,060, 1,020, 969 and 914 for  $\delta$ OH (Fig. 1B, curves 1 and 2). Since the 3,420  $\text{cm}^{-1}$  band is very sharp but not so intense, it cannot be considered to correspond to the very strong 3,428  $\text{cm}^{-1}$  band reported in the literature<sup>1,2</sup>.

The main difference in the two spectra of the present samples occurs at three points: First, the single crystal shows no band at 3,460  $\text{cm}^{-1}$  while the powdered sample has a strong one. The 3,520  $\text{cm}^{-1}$  band of the crystal is very intense and somewhat broad, while the corresponding peak of the powder is sharper and lower in intensity. Secondly, the 1,060  $\text{cm}^{-1}$  band, which is very strong in the spectrum of the crystal, is considerably weakened or diminished in the spectrum of the powder. Finally, the 560  $\text{cm}^{-1}$  band is characteristic for the powder, but absent in the spectrum of the crystal.

The dependency of these bands on the period of grinding was examined. The intensity ratio of the 3,460  $\text{cm}^{-1}$  band to the 3,520  $\text{cm}^{-1}$  band was found to increase as the period of grinding increased, while the 1,060  $\text{cm}^{-1}$  band was extremely weakened. It is probable that these powdering effects are not due to any increase in the surface hydroxyl group, since this is estimated to be very small compared with that of inner lattice sites. It is more likely that these effects are due to crystal deformation by the mechanical stress during the grinding.

We thank A. Kato, of the Science Museum in Tokyo, for providing the samples.

### Variance as a Measure of Line Broadening : Particle-size Determination

THE X-ray determination of the average particle size in a polycrystalline aggregate, using the variance as a measure of line breadth, gives two independent estimates of the average size<sup>1</sup>. The variance of the line (corrected for the background<sup>2</sup>) varies linearly with the range of scan in the region where the intensity decreases as the inverse square of the range. The slope of this linear function, after subtracting the contribution from the emission-spectrum variance, is inversely proportional to the apparent particle size, provided that the specimen is well annealed and free from 'mistakes'. The apparent size calculated from the slope is the same as that determined by the Fourier method<sup>3</sup>, and is the mean thickness of the crystallites measured perpendicular to the reflecting planes<sup>4</sup>. (The integral breadth, however, gives a slightly higher apparent size, this being the volume average of the thickness of the crystal, again in the direction normal to the reflecting planes<sup>5</sup>.) The 'true' size (the cube root of the volume) is the product of the apparent size and the appropriate Scherrer constant<sup>1,6</sup>.

The intercept of the linear variance-range function is inversely proportional to the square of what may be regarded as another apparent size. The ratio of the true size to this apparent value is  $\sqrt{L}$ , where  $L$  is the taper parameter<sup>1</sup>.  $L$  is a measure of the angularity, or rate of taper, of the crystallites, and has values in the range

0.3 for the regular shapes considered by Wilson<sup>1</sup>. The taper parameter displays a wider variation than the Scherrer constant for different  $hkl$  planes, and if the intercepts of the variance function are determined for several reflexions, information about the shape of the crystallites is obtained, as well as the average size.

The particle size in an annealed nickel powder has been measured using the variance method—the linear variance-range functions being obtained for the first eight reflexions. The intercepts and slopes of these functions were in each case corrected for the effect of truncation of the integrated intensity (ref. 8, equation 8). The apparent size, based on the slope, ranges from 77 Å to 115 Å. For each reflexion, the true size can be calculated on the assumption that the shape of the particles is spherical, cubic, tetrahedral or octahedral<sup>1</sup>. This estimate of the size, for a particular value of  $hkl$ , is to some extent dependent on the assumed shape, and in this case the Scherrer constant for tetrahedra gives the most consistent value of the true size ( $180 \pm 30$  Å). Since the 'slope size' averaged for all  $hkl$  is relatively independent of the assumed shape for crystallites of the face-centred cubic system, the value of 180 Å is probably close to the actual (average) particle size. (The standard deviation of 30 Å is partly a measure of the experimental error, but it also includes the scatter introduced by the assumption that all particles are of the same size and shape.)

It was found that the variance-range functions had a significant negative intercept for all  $hkl$ , and it was immediately apparent that the particles are far from spherical. The effective apparent size is in the range 83 Å–120 Å, and of the foregoing shapes, using the appropriate taper parameters, tetrahedra again give the most consistent estimate of the true size ( $140 \pm 20$  Å). Unlike the value determined from the slopes, the 'intercept size', averaged for all  $hkl$ , is strongly dependent on the shape, as is evident from Wilson's Table 2 (ref. 1). The low average value obtained from the intercepts in fact indicates that the crystallites taper more rapidly (that is, are more angular) than tetrahedra.

An average size of 220 Å was obtained by direct measurement from electron micrographs, which agrees well with the size determined by X-ray methods. The crystallites were also observed to be angular and irregular. However, the assumption of a regular shape for the purpose of calculating the average size gives a reasonable estimate of the actual value.

I thank Prof. A. J. C. Wilson for his assistance and Mr. G. K. Rickards, of the Central Electricity Generating Board Nuclear Laboratory, Berkeley, for providing the electron micrographs.

## GEOPHYSICS

### Travel-time Tables for the Seismic Wave PKP

RECENTLY I published some contributions<sup>1,2</sup> on the problem of the structure of the Earth's core. In the course of this work a considerable amount of observational material on the seismic core phase PKP was exam-

ined and empirical seismological travel-time tables for two branches of the PKP curve were derived from the observations. A number of seismologists have suggested that it would be useful to them if such tables were published.

Revised PKP travel-times are required for two main purposes: in order to derive the structural detail within the core, and in routine computer location of hypocentres of earthquakes. In the latter problem, because of the relatively small gradient of the travel-time curve, PKP observations provide a valuable constraint on origin-time and focal-depth.

In this communication my present estimates of the average-travel-times of PKP are tabulated in Table 1. The general level of the curves is tied to the *P* travel-time tables of Jeffreys and Bullen<sup>3</sup>. This standardization is achieved for each earthquake by adjusting the observed PKP times by the mean residual  $\delta$  from the Jeffreys-Bullen tables for *P* observations at distances of  $40^\circ < \Delta < 105^\circ$ . This procedure minimizes errors in the estimation of focal-depth and relates Table 1 directly to the standard spherical Earth model with a continental crust of 33 km.

Table 1. TRAVEL-TIMES OF PKP

$\Delta$ deg	(Surface focus)		GH branch (m) (s)
	DEF branch (m) (s)		
110	D 18	35.0	
115		44.6	
120		54.1	
125	19	2.7	G (18 41.7)
130		13.3	18 55.5
135		23.6	19 9.2
140	(19	33.1)	19 23.9
145	(19	40.6)	19 36.4
150		48.8	(later than DEF)
155		56.9	
160	20	02.0	
165		06.9	
170		10.4	
175		13.4	
180	F 20	13.0	

The listed times are for the two branches of the PKP curve denoted by DEF and GH (Fig. 2, ref. 2). DEF gives the times for the longitudinal waves PKIKP which penetrate the terrestrial inner core. The branch GH has been interpreted<sup>1</sup> as arising from longitudinal waves PKHKP, which are refracted into an intermediate shell which separates the liquid outer core from the solid inner core.

Values are given at intervals of  $5^\circ$  allowing interpolation from the first differences only. Adjustments for focal depth are, of course, identical with those given in the Jeffreys-Bullen tables. The times in parentheses are not directly from observations in the corresponding distance range but are interpolations. At distances greater than  $150^\circ$ , PKHKP arrives later than the PKIKP phase; the material used to derive Table 1 did not yield usefully precise values for this portion of the GH curve.

The PKP curves were derived as follows:

**The branch DEF.** In the range  $110^\circ < \Delta < 140^\circ$ , the times in Table 1 are means of three independent sets of measurements. (1) Times of PKIKP to North American and European stations from 24 selected earthquakes in southern Asia and the Pacific provide the most numerous material<sup>4</sup>. A least-squares analysis of these data led to a linear relation with a gradient of 1.92 sec/deg in the entire distance range and a standard error for one observation,  $\sigma$ , equal to 2.4 sec. (2) A series of shallow-focus Aleutian earthquakes in 1957 provided a linear equation for the PKP times to African observatories<sup>5</sup> in the range  $126^\circ < \Delta < 137^\circ$ . The gradient was 1.80 sec/deg and  $\sigma = 2.0$  sec; the maximum time difference between this solution and the one for the Pacific earthquakes was 0.6 sec.

At distances between  $140^\circ$  and  $150^\circ$ , the branches AB (this branch is generated by the PKP<sub>1</sub> waves), DEF and

GH of the PKP curve intersect so that allocation of a wave onset to its proper branch is very difficult; resolution is further obscured by the caustic at the cusp at B. (3) Values of times of PKIKP for  $\Delta > 150^\circ$  were found from measurements<sup>8</sup> of the times of this phase from the deep-focus New Zealand earthquake of December 10, 1958. More than 70 travel-times were available in the ranges  $118^\circ < \Delta < 130^\circ$  and  $146^\circ < \Delta < 180^\circ$ . A cubic polynomial, fitted by least squares, yielded  $\sigma = 1.9$  sec. The cubic joins smoothly on to the linear curve from the 24 southern earthquakes at  $135^\circ$ . The close agreement between the three independent curves at distances of  $125^\circ < \Delta < 135^\circ$  provides the justification for combining them to obtain the single solution given in Table 1.

*The branch GH.* A reliable set of measurements<sup>3</sup> is available from readings of PKHKP at North American stations from the deep-focus Java Sea earthquake of April 16, 1957. Only times from stations with  $127^\circ < \Delta < 139^\circ$  were used although there is evidence that a faster wave path exists for distances as small as  $123^\circ$ . Some weight in the computation of the mean values for GH in Table 1 was also given to observations of the precursor to PKIKP summarized in the study of the 24 southern earthquakes<sup>4</sup>.

Travel-times for GH are not given in the Jeffreys-Bullen tables. The times for DFF in Table 1 are later by 1.8 to 0.8 sec than the corresponding times given by Jeffreys and Bullen. The latter times for  $\Delta < 145^\circ$  are based on an analysis of PKP readings from the deep-focus earthquake of January 9, 1932. A subsequent check of these times was made by Jeffreys<sup>8</sup> using observations from the deep-focus earthquake of June 29, 1934; of his two solutions, the preferred one gave a mean of

+1.2 sec for PKIKP residuals at  $\Delta < 140^\circ$  with a standard error of 0.25 sec. This adjustment, which would give close agreement with the values in Table 1, was not, however, incorporated into the Jeffreys-Bullen tables.

'Calibration' of the values at some distances in Table 1, all of which are derived from earthquake data, is possible from recorded PKP transmission times from surface Pacific nuclear explosions with known shot-times<sup>7</sup>. A search of the catalogues of the *International Seismological Summary* and the *Bureau Central International Seismologique* shows that only the shots listed in Table 2 provided PKP onsets which were measured routinely.

Although a number of stations recorded several PKP phases from a single shot, only the time of the first onset has been used here. The 16 PKP measurements from the 1954 series at Bikini have been discussed already by a number of authors, so that only the over-all mean at each recording station is listed in Table 3; the remaining 23 observations, not previously summarized, are tabulated in full.

To allow direct comparison with the earthquake data the observed PKP times for each shot must be adjusted to the standard reference Earth. The adjustment  $\delta$  was found in previous work<sup>1</sup> to be -1.8 sec for a surface source at Bikini atoll. In the absence of evidence to the contrary the same value is adopted for Eniwetok atoll.

The Wigwam shot occurred under water 4 km above the abyssal plains of the eastern Pacific. P readings at 12 stations with  $70^\circ < \Delta < 100^\circ$  have a mean  $\delta$  equal to 0.0 sec. The differences between this adjustment and that for the other explosions can be explained readily in terms of

the differing  $P$  velocity in water (1.4 km/sec) and the rock under the atolls (5.1 km/sec).

In Table 3 the observed  $PKP$  times, after adjustment for  $\delta$  and ellipticity, are compared with the Jeffreys-Bullen tables for the  $DEF$  branch and with Table 1. At all distances involved, the former tables, on the average, lead to larger residuals than do the new tables. The largest residual of 7 sec comes from an apparently late reading at Paris of  $PKP$  from the Wahoo shot. On rejection of this observation the 21 onsets identified as  $PKIP$  give a mean residual against Table 1 of  $-0.4 \pm 0.4$  sec; the 18 onsets taken to be  $PKHKP$  give  $0.7 \pm 0.5$  sec. Both mean residuals do not differ significantly from zero so that these nuclear explosion data do not suggest any further revision in the  $PKP$  tables.

Inter-comparison between the independent sets of observations used to derive Table 1 allows an assessment of the general accuracy. The greatest uncertainty in the mean values is probably in the values for  $GH$ . Wave energies for this branch are relatively weak and the phase is often missed. The 18 travel-times with  $136^\circ < \Delta < 141^\circ$  from the Pacific explosions yield a standard error of  $\sigma = 2.2$  sec. (The tables for  $GH$  may encourage publication of observations of this phase in station bulletins.) Average times for  $PKIP$  at  $\Delta < 140^\circ$  in the standard Earth model are now probably known within 1 sec; standard errors calculated from the independent populations considered for the times of  $DE$  are of order 2 sec. The standard error for one  $PKIP$  observation for  $\Delta > 150^\circ$  is about 2 sec. Many of the  $PKP$  observations which were made near the antipode from the 1958 New Zealand earthquake come from stations on the Iberian Peninsula, some of which were not well equipped at the time. However, most measurements are consistent between adjacent stations. For  $\Delta > 147^\circ$ , for example, only six of the 55 observations had residuals from the Jeffreys-Bullen tables exceeding 4 sec in magnitude. If these six are rejected the standard error for one observation falls to 1.5 sec and the corresponding travel-times in Table 1 are reduced by two-tenths of 1 sec.

In conclusion, it should be stressed that the revised  $PKP$  tables represent smoothed empirical times. They do not depend on any particular assumed velocity distribution within the core. However, the velocity distribution called  $T2$  which I have derived<sup>1</sup> predicts the times in Table 1 to about 1 sec.

### Terrestrial Control in the Production of Aurora

AMPLE evidence exists for a physical connexion of some kind between certain solar events, typified by a flare, and such related phenomena as disturbances in the Earth's magnetic field and in the ionosphere, and the occurrence of aurora. A variety of model mechanisms has been proposed to describe the links in the chain of connexion. But whether they invoke a stream of particles emanating from the active solar area or an elongated envelope of solar magnetic field anchored on the area for the first stage in

the linkage from the Sun, few of the models continue the mechanism in detail nearer the Earth than the outer confines of the magnetosphere. There are defects in any model which tries to continue the particle stream directly down to auroral level in the Earth's atmosphere using the geomagnetic field as guide lines; and to introduce the outer radiation belt as an intermediate stage has incurred the difficulty, at least according to present notions, that the energy which can be stored there is inadequate to sustain great auroral displays.

As part of the difficulty in completing the chain of events is attributable to lack of observational evidence for supporting either a direct or indirect connexion between the Sun and the Earth's atmosphere, it may be useful to summarize a few aspects of auroral activity which are relevant to the problem. These were noted<sup>1</sup> at Fort Rae, north-west Canada, during the second polar year 1932-33.

The main evidence lies in the occurrence of clear-cut departures in the development of auroral displays on two or more successive nights from the pattern of development on a majority of nights. Ignoring colour effects the average pattern to which most displays tended to conform was broadly as follows: after a more-or-less diffuse homogeneous arc had persisted quietly for several hours from evening twilight it began to disintegrate into separate bands with vertical ray structure. The change to bands of rays was at first slow, but after a few minutes the whole scene became more active and filled the sky in a series of rapid transformations. The rays extended vertically, brightened, and moved about in bundles with progressively increasing speed and intensity of brightness, the movements being both to-and-fro in an east-west (magnetic) plane and in wave-like movements out and in from that plane. At this stage the rays extended towards the zenith forming a sheet of curtains or draperies traversed by rapid waves. This violent phase, which sometimes culminated in a corona lasting a few seconds, was short-lived: the whole display quickly degenerated. The rayed curtains became diffuse and increasingly confused and sluggish in movement; they fell back from the zenith to merge together in a ragged band or confused glow lower in the sky. For a time, of the order of a minute, the part of the upper sky where the activity had been concentrated was suffused with a tangled mass of luminescence which quickly became uniform and faded.

This cycle of high activity frequently repeated itself several times in quick succession within one night's display, but on the average such short-life outbursts did not affect the basic pattern: long and slow development, rapid culmination to violently active rayed structures, followed by a quick transition back to a protracted decay. The distribution of activity in time was such that any one display could span continuously the 16 h from dusk around 4 p.m. to dawn at 8 a.m. and the active phase occurred at any time in the 5-h period centred 0.5 h before midnight. The point to be inferred from the foregoing 'identikit' sketch is that although there were differences, sometimes considerable, from night to night in the intensity and time of the most violent phase, enough of a basic generic resemblance subsisted throughout the displays of the 1932-33 season at Fort Rae to allow departures from the average pattern to become immediately noticeable. It is these unusual features in the development of displays on two or more consecutive nights, and particularly the similarity of auroral behaviour at approximately the same time on these consecutive nights, which seem to provide evidence for a terrestrial control in the mechanism producing the aurora. The repetitions of detailed behaviour were the more striking in that they occurred at times when, according to the average pattern of development, quite other phases of the display should have been in progress. The following examples were noted:

(1) February 23 and 24, 1933. The climax was reached on both nights between 23 h 5 m and 23 h 30 m L.T., and

took almost identical form—particularly long-rayed curtains in violent motion. Similar concentrations of activity occurred on February 26 and 27 between 21 h 50 m and 22 h 15 m and again on March 2 and 3 between 23 h 35 m and 23 h 40 m.

(2) In contrast with the usual first appearance of aurora in the form of a diffuse quiet arc or low glow, the displays on August 18 and 19, 1932, started at about the same time with multiple arc systems overhead or slightly south of the magnetic prime vertical plane. Subsequent developments on both nights were also similar and different from normal.

(3) December 28 and 29, 1932. A homogeneous arc which had persisted quietly for many hours quickly disintegrated at precisely the same time on both nights (5 h 55 m L.T.). A similar feature occurred on December 31, 1932, and January 1, 1933.

(4) On the evenings both before and after January 8 and 9, 1933, aurora was noted as soon as twilight was weak enough, about 16 h L.T. But, though the sky was almost cloudless, aurora was not observed until 19 h 45 m on January 8 and 19 h 30 m on January 9. Instead of the normally continuous display after the start, a period without activity intervened at 21 h.

(5) August 8 and 9, 1932. On those nights features differing from the average pattern were repeated at about the same times. Both displays began between 20 h 45 m and 21 h 15 m L.T. with band forms in the south-south-east sky. These persisted until 22 h 15 m when, after a brief lull in activity on both nights, arcs appeared across the zenith: these quickly dissipated, to be followed by another interlude of weak aurora. From 22 h 45 m until 23 h 45 m the most active phase occurred, culminating in a corona on both evenings. A further lull intervened 15 min after midnight, followed by another outburst.

(6) Well-developed and clearly defined coronas occurred infrequently. Although aurora of one form or another was observed at Fort Rae for more than 1,500 h during the 1932–33 season, the total duration of all coronas probably did not exceed 10 min. If in those circumstances a corona appeared about the same time within a few minutes on consecutive evenings, there was reason for regarding the feature as unusual, more especially when, on other occasions, a corona did form as early as 21 h on one evening and as late as 3 a.m. in the next night's display. On September 9 and 10, 1932, coronas formed at 1 h 17 m, 1 h 50 m and 2 h 3 m. On other pairs of consecutive days of the same month they appeared at 22 h 45 m and 23 h 13 m. Variants of this kind of repetition occurred on other pairs of days separated by one day.

In the face of those examples it is difficult to accept any mechanism for the production of aurora which has not one constituent at least partially within the Earth's control. Despite present assessments that its stored energy is unable to account for prolonged displays the most likely intermediary is the outer radiation belt. Besides being amenable to explain the local time repetition of particular auroral features on consecutive days, it can assume again the role attributed to it a few years ago and since withdrawn, the role of serving as a local reservoir for auroral particles even in the Sun's least active times. That this is an important requirement of any mechanism may also be inferred from the Fort Rae data. Although 1932–33 was a period of very low solar activity, aurora was observed on 242 out of 270 nights in the one season, mid-August to mid-May, and the sky was obscured by cloud on the other 28 nights.

### Comparison of the Diurnal Variation of the Horizontal Component of the Earth's Magnetic Field at Nairobi with that at Addis Ababa

THE small magnetic observatory at University College, Nairobi, was completed in time for the International Quiet Sun Year. The station is equipped with three component La Cour variometers and is standardized by means of two quartz horizontal force magnetometers and a magnetometric zero balance. These instruments were compared with standard instruments in March 1963 by Laursen and again in December 1964 by Wienert. Observations for the first year of operation are being analysed and the results for the diurnal variation in horizontal component  $H$  during the months of April and May 1964 are given here for comparison with similar data from Addis Ababa for the same period.

The geographical co-ordinates of the station are  $36^{\circ}82' \text{ E.}$ ,  $1^{\circ}32' \text{ S.}$ , the latitude being approximately  $10^{\circ}5' \text{ S.}$  of the magnetic dip equator, which in East Africa passes close to Addis Ababa. The measured dip of  $26^{\circ}9' \text{ S.}$  compares with the  $26^{\circ}7' \text{ S.}$  found by Whitham and Hoge<sup>1</sup> in 1959 for another site in Nairobi. The station is thus well outside the main influence of the electrojet<sup>2</sup> so that it is of interest to compare the diurnal variation in  $H$  with that observed close to the electrojet at Addis Ababa. Local time is similar at the two stations so that records may be directly compared (longitude Addis Ababa  $38^{\circ}46' \text{ E.}$  Both stations use Greenwich Mean Time plus 3 h). Fig. 1 shows plots of the mean hourly ranges for the months of April and May 1964 for 9 quiet days and 8 disturbed days at Nairobi and for the same days at Addis Ababa, together with the difference between the disturbed and quiet day values. We define the hourly ranges as the departures in  $H$  from the mean midnight value for the day (the mean midnight value being taken as the mean of the values for the hours of 01 and 24 for the same day). The diurnal range is the maximum departure from this midnight value.

It will be noted that the maximum ranges occur close to noon and that, although the Addis Ababa noon range is substantially greater than that for Nairobi on quiet days, the noon ranges at the two stations are similar for disturbed days. A greater difference exists between the disturbed and quiet day curves at Nairobi than is the case for Addis Ababa, and a pronounced maximum occurs in the records from both stations at approximately 03 h on disturbed days: Onwumechilli<sup>3</sup> notes that indentations occur simultaneously at stations of differing latitude near the equator. The Nairobi records throughout the year show similar features on disturbed days.

Whitham and Hoge<sup>1</sup> comment on the large diurnal range in East Africa, and this is in agreement with previous investigations<sup>4,5</sup>. For the period under consideration we find that the mean quiet day range is 57% compared with the 76% found at Addis Ababa. The ratio of the diurnal variation at Nairobi to that at Addis Ababa is about 0.75.

Unfortunately several different definitions of daily range are in use, and this makes it more difficult to compare our results with those obtained elsewhere than would otherwise be the case. Onwumechilli<sup>3</sup> has measured the total diurnal range in  $H$  (that is, the difference between the minimum and maximum values) as a function of latitude at a number of field stations in West Africa during the period November 1956–January 1957. His measurements extend only to about  $4^{\circ}$  on either side of the dip equator; he finds that the ratio of the total range at a station of about  $4^{\circ}$  dip latitude to that observed near the dip equator is approximately 0.55. The value of this ratio between Nairobi and Addis Ababa for quiet days in April and May 1964 is about 0.8 and is considerably higher than one would expect from Onwumechilli's observations. Onwumechilli<sup>3</sup> also estimates a total quiet-day

Fig. 1. a, Nairobi, ●, quiet; ○, disturbed; b, Addis Ababa, ●, quiet; ○, disturbed; c, disturbed less quiet values, +, Nairobi; Δ, Addis Ababa

diurnal range in  $H$  of  $64\gamma$  at the geographical equator by assuming a parabolic relation for the variation with latitude of the quiet day normal field (that is, the field not including the influence of the electrojet). The value found by us for the total quiet-day range at Nairobi for sunspot minimum is  $85\gamma$ . Data published for Addis Ababa<sup>5</sup> suggest that the daily range at sunspot minimum is about 60 per cent of that at sunspot maximum and thus lend support to the idea that the daily range is high at Nairobi.

Vestine *et al.*<sup>6</sup> quote 95–100 $\gamma$  for the total diurnal range on the geographical equator, averaged for the months of April and May over the period 1922–1933. Forbush and Casaverde<sup>7</sup> give curves which suggest a range of  $95\gamma$  for a station  $10^\circ$  from the dip equator and  $210\gamma$  for a station near the dip equator in Peru and at sunspot maximum; the value for the total range at Addis Ababa in 1958 is  $175\gamma$  (ref. 5). Whitham and Hoge<sup>1</sup> give curves for 5 quiet, 5 disturbed and 24 other days which show an average total diurnal range of  $120\gamma$  in March and April 1959 in Nairobi. The disturbed day total range at Nairobi for April and May 1964 is  $92\gamma$  and is substantially greater than the  $71\gamma$  observed at Addis Ababa.

The adoption of a standard definition of daily range would much simplify the comparison of data from different stations. Further comparisons of the data from Nairobi and Addis Ababa will be continued in order to obtain more reliable information and comparison of the seasonal effects.

We thank Dr. J. Stagg for setting up the variometers in December 1963 and for Leverhulme funds given for this purpose by the Royal Society. We also thank Dr. P. Mohr for supplying the Addis Ababa data and Dr. V. Laursen and Dr. K. Wienert for their advice. This work was also supported by the Rockefeller Foundation.

## MINERALOGY

### Stilpnomelane from the Dalradian

STILPNOMELANE has been found as a constituent of the schists of many low-grade areas throughout the world<sup>1–3</sup>. In the Dalradian it has been described from the South-west Highland epidiorites<sup>4–6</sup> but not from the greywackes and pelites of the Upper Dalradian, although it is mentioned as occurring in "the quartz-feldspathic green schists of the Southern Dalradian" by Voll<sup>7</sup>.

Two distinct members of the stilpnomelane group of minerals have been found in the Ben Ledi Grits of the Highland Border area. They occur in association with albite, microcline, quartz, muscovite and chlorite north-west of Aberfoyle in Perthshire.

On the basis of their pleochroism, the Dalradian stilpnomelanes may be divided into green varieties, rich in ferro-stilpnomelane, and brown varieties, rich in ferristilpnomelane. Pleochroism is strong with axial colours as follows. Ferro-stilpnomelane:  $\alpha$  = very pale yellow to pale yellow,  $\beta = \gamma$  = pale green to olive green; ferristilpnomelane:  $\alpha$  = pale golden yellow,  $\beta = \gamma$  = dark brown.

The stilpnomelane occurs either as radiating clusters lying in and across the schistosity planes or as thin scales wrapped around and embaying quartz and feldspar grains. Some microcline grains are completely replaced by finger-like growths of stilpnomelane which project into and grow within them. Stilpnomelane occurs in the grits both as the only ferromagnesian phase and as an accessory constituent in the more common assemblage, albite-microcline-quartz-muscovite-chlorite.

Table 1 lists the X-ray powder data for a brown stilpnomelane from a grit to the north of the slate belt. The measurements were obtained using a Debye-Scherrer camera, filtered cobalt radiation and a small amount of quartz as an internal standard. The data are tabulated alongside that of Gruner<sup>8</sup> for a brown stilpnomelane from Baern, Moravia. Unfiltered iron radiation was used, but in tabulating the data the lines due to  $K\beta$  have been ignored. The powder photograph also contains other lines, notably one at  $8.20 \text{ \AA}$ . The origin of these is not clear, but they may be spurious peaks as the X-rays were filtered but not otherwise monochromatized<sup>9</sup>. The basal spacing  $12.1 \text{ \AA}$  agrees with that of Gruner<sup>8,10</sup> and Hutton<sup>1</sup>.

Apart from the Aberfoyle area, stilpnomelane has been found as an abundant mineral in a grit from the Lemy

## GEOCHEMISTRY

### Oxygen Isotope Fractionation between Coexisting Calcite and Dolomite in the Freshwater Upper Carboniferous Freeport Formation

HYDROTHERMAL experiments of Epstein, Graf and Degens<sup>1</sup> have suggested that dolomite forms from pre-existing calcite by a replacement mechanism in which the  $^{18}\text{O}/^{16}\text{O}$  ratio of the original calcite remains unchanged. In an investigation of natural sedimentary dolomite-calcite rocks, Degens and Epstein<sup>2</sup> observed no fractionation of the oxygen isotopes between coexisting calcite and dolomite in relatively young deposits and concluded that all dolomite is secondary, that is a replacement product of pre-existing calcite. Older carbonate rocks examined by those authors, however, did contain dolomite which was enriched in oxygen-18 with respect to the associated calcite. This phenomenon was explained by possible isotopic equilibration of the calcite with intrastatal fluids (which are generally enriched in oxygen-16). Dolomite is believed to be more resistant to equilibration. Hence, according to Degens and Epstein, such calcite rocks are partly replaced by diagenetic dolomite without alteration of the isotopic composition of the carbonate. With time, oxygen isotope exchange between formation waters and the calcite, but to a negligible extent between the waters and the dolomite, results in a higher  $^{18}\text{O}/^{16}\text{O}$  ratio in the dolomite. Thus the difference in  $\delta^{18}\text{O}_{\text{dol}}$  and  $\delta^{18}\text{O}_{\text{cal}}$  ob-

served in ancient carbonate rocks does not represent original isotopic equilibrium between these two minerals.

Although the mechanisms postulated by Degens and Epstein are possible, there is some doubt as to whether 'all' dolomite deposits have been formed in this manner, and indeed, if even most of the fine-grained dolomites have such an origin. The question is an important one since problems concerning the evolution of the oceans and possible extension of the oxygen isotope palaeogeothermometer to older rocks are involved<sup>3</sup>. For this reason, a number of occurrences of very fine-grained, dense, compact carbonate rocks of freshwater origin are being examined on the basis of a working hypothesis that: (1) dolomite in such deposits originated soon after deposition of the calcite, before consolidation and lithification of the sediments, and (2) the slow growth of authigenic dolomite permitted oxygen isotope equilibrium between the two minerals. Observations consistent with this hypothesis would comprise: (1) oxygen-18 enrichment in dolomite with respect to calcite in the order of 5 to 8 per mil, (2)  $\delta^{18}\text{O}$  values for calcite in the range of present freshwater calcites, and (3)  $\delta^{18}\text{O}$  values for dolomite significantly greater (more positive) than those of present freshwater calcites. If the  $^{18}\text{O}/^{16}\text{O}$  ratios of a reasonable sampling of freshwater dolomitic limestones are not much different from modern freshwater calcites, then the conclusions of Degens and Epstein would seem valid.

The results of an investigation of the dolomite-calcite micrites of the Palaeocene-Eocene Flagstaff formation (central Utah) have already been reported<sup>4</sup>:  $\delta^{18}\text{O}_{\text{cal}} = -9$  to  $-10$  per mil, and  $\delta^{18}\text{O}_{\text{dol}} = -3$  to  $-4$  per mil relative to the PDB standard carbon dioxide. These values may be compared with the isotopic composition of eleven freshwater calcium carbonates of Quaternary age (mean  $-8.15$  per mil, *S.D.* 2.08) and 63 of Tertiary age<sup>5</sup> (mean  $-9.65$ , *S.D.* 4.48).

The fine-grained dolomitic limestones of the Freeport formation (Upper Carboniferous) outcropping over an area of about 100 square miles in central Pennsylvania constitute the second examination of this nature. The freshwater depositional environment is established by the presence of freshwater ostracods, *Spirorbis*, *Carbonicola* and other freshwater fossils, as well as by detailed palaeogeographic reconstruction. The fine-grained nature of the coexisting carbonates precludes physical separation of the calcite and the dolomite. The Degens and Epstein method of differential extraction of carbon dioxide based on the difference in the reactivity rate of these carbonates with phosphoric acid cannot be applied because of the presence of siderite in the Freeport samples. To obtain the values of  $\delta^{18}\text{O}_{\text{cal}}$  and  $\delta^{18}\text{O}_{\text{dol}}$ , a number of samples from each collecting site were analysed to obtain  $\delta^{18}\text{O}$  for the bulk carbonate, that is a mixture of calcite, dolomite and siderite. The mineral composition of the rock was obtained by quantitative X-ray diffraction (I thank Dr. R. E. Bergenback for collection of the samples and for quantitative X-ray diffraction data), and  $\delta^{18}\text{O}$  bulk was plotted against percentage of calcite, percentage of siderite and percentage of dolomite by fitting a least squares plane to the data (multiple linear regression). Extrapolation of the plane to 100 per cent calcite and 100 per cent dolomite provides the isotopic composition of each of these minerals. The equation is of the form,  $Y = a + bX_1 + cX_2 + dX_3$ , where  $Y = \delta^{18}\text{O}$ ;  $X_1$ ,  $X_2$ , and  $X_3$  = percentage of calcite, siderite and dolomite, respectively;  $a$ ,  $b$ ,  $c$ , and  $d$  are constants. The isotopic composition of calcite, for example, is calculated by setting  $X_1 = 100$ ,  $X_2 = X_3 = 0$ , and solving for  $Y$ . One hundred and thirty-two samples were analysed (by standard techniques, see ref. 5: precision, represented by the standard deviation, is 0.05 per mil) and the data from any given site were discarded if the coefficient of multiple correlation was not significant at the 1 per cent level. Failure to fit an adequate regression plane to the data may arise because of insufficient variation in mineralogical composition among the samples from one site, or

because  $\delta^{18}\text{O}_{\text{ct}}$  and/or  $\delta^{18}\text{O}_{\text{dol}}$  were not constant over the few feet in the stratigraphic section from which the samples were taken.

Even including the results when the multiple linear regression curve did not account for the variation in the four variables ( $Y$ ,  $X_1$ ,  $X_2$ ,  $X_3$ ) to an acceptable degree (that is, the 1 per cent level of significance) the dolomite was invariably enriched in  $^{18}\text{O}$ . Mean values for the six collecting sites where the coefficient of multiple correlation was highest are:  $\delta^{18}\text{O}_{\text{ct}} = -7.87$  permil;  $\delta^{18}\text{O}_{\text{dol}} = -3.04$  permil;  $\delta^{18}\text{O}_{\text{dol}} - \delta^{18}\text{O}_{\text{ct}} = 4.83$ . Both the Flagstaff and the Freeport data support the working hypothesis; the dolomite is relatively enriched in oxygen-18 with respect to modern and Tertiary calcites. If further investigations of freshwater carbonates substantiate these findings, equilibration of the oxygen isotopes of calcite and dolomite prior to lithification may be indicated.

## CHEMISTRY

### Polythene-backed Paper for High-voltage Electrophoresis

THE improvement of technique achieved in zone electrophoresis through the use of potential gradients up to 150 V/cm has been found to be partially offset by difficulties of manipulation due to the poor wet strength of conventional papers. The marketing of 'Benchkote' (Whatman) sold by H. Reeve Angel and Co., Ltd., 9 Bridewell Place, London, E.C.4, in rolls 45 cm  $\times$  50 m), a polythene-backed filter paper (primarily intended as a protective covering for benches) of very high wet strength, prompted the tests described here, to determine if such a material would exploit the advantages of high-voltage electrophoresis to the fullest extent.

The trials described were performed using a 'Virus' high-voltage electrophoresis apparatus (supplied by Dr. Virus KG, Rosenbergweg 20, Bonn). This instrument requires that the paper medium (dimensions 100 cm  $\times$  45 cm) be soaked in buffer, that excess buffer be squeezed out by passage through rollers and then that it be stretched tightly over a cooled glass plate. The potential is applied through buffer chambers (set 60 cm apart) making contact with the paper through sintered glass moistened with the buffer. Failure to remove excess buffer or to make good contact with the cold glass surface negates the advantages gained by using a high voltage to bring about the resolution desired. The increased wet strength given by the polythene backing of 'Benchkote' makes it a superior material for that series of manipulations, when compared with ordinary chromatographic paper. An added advantage is that the polythene backing prevents water, condensed from the atmosphere on to the cold glass surface, being taken up into the paper.

When 'Benchkote' is soaked with buffer the paper swells but the polythene does not, and it has been found best to blot off most of the excess buffer before squeezing through the rollers. Also the 'Benchkote' should be fed into the rollers paper side down and from above, so that the buffer squeezed out drains off the bottom roller and cannot flood the incoming sheet.

The prepared paper is almost dry to the touch. Electrophoresis has been carried out with potential gradients up to 130 V/cm (the limit of the power pack), but the usual

conditions were 80 V/cm with a maximum current of 40 mA and a cooling plate temperature of 1° C.

Most of the work done using 'Benchkote' in this way has been to study the nucleotides produced by the action of acid on yeast RNA. The resolution has been improved relative to other electrophoretic techniques used formerly and only one-quarter of the time is required for an analysis. Substances which absorb ultra-violet light have been detected using 2537 Å illumination (from a low-pressure mercury arc<sup>1</sup>) with the same ease and sensitivity as on ordinary paper.

Tests of the method have also been made running amino-acid separations, and the gain in resolving power reported previously<sup>2</sup> has been seen. The ninhydrin reagent works effectively for the detection.

Other spray reagents involving heating the electrophoretogram may also be used, as temperatures of 100° C do not damage 'Benchkote' unless the exposure is unduly prolonged, when the softening polythene gives a permanent warp.

Polythene-backed paper has considerable advantages for the kind of work described. The results obtained with 'Benchkote' and the versatility of the technique may be improved by bonding to polythene a range of papers of truly chromatographic quality. (Messrs. Reeve Angel have kindly given me a sample of polythene-backed Whatman No. 3MM paper; polythene-backed papers of chromatographic quality may become commercially available later. They warn that 'Benchkote' is marketed as a bench covering, and that due to the tolerances to which it is manufactured its performance in paper electrophoresis may be variable. A suitable standard ought therefore to be included on each electrophoretogram.)

### Al-Fe Isomorphic Substitution in 3 CaO-Al<sub>2</sub>O<sub>3</sub> and 2 CaO.Fe<sub>2</sub>O<sub>3</sub>, and Interactions between the So-called C<sub>3</sub>A and C<sub>4</sub>AF Phases

THE isomorphic replacement of iron by aluminium in 2 CaO.Fe<sub>2</sub>O<sub>3</sub> has been widely investigated, but much less attention has been directed to the introduction of iron in the structure of 3 CaO.Al<sub>2</sub>O<sub>3</sub>.

A recent investigation by Schlaudt and Roy<sup>1</sup> led to the conclusion that, at 1,389° C, a maximum of 3.5 moles per cent Fe<sub>2</sub>O<sub>3</sub> can be substituted for Al<sub>2</sub>O<sub>3</sub> in 3 CaO.Al<sub>2</sub>O<sub>3</sub>, leading to the limiting solid solution 3 CaO.(Al<sub>0.985</sub>Fe<sub>0.015</sub>)<sub>2</sub>O<sub>3</sub>. This amount is still lower for different (higher or lower) temperatures.

Work carried out in this laboratory by X-ray diffraction and infra-red absorption spectroscopy is not in accordance with this limiting composition.

The observed 2θ diffraction angles have been plotted as a function of composition for 3 diffraction lines of high indices (lines 8.8.0, 12.4.0 and 12.8.4; C.G.R. diffractometer; iron K $\alpha$  radiation). For the 3 lines, a regular decrease of the 2θ values is observed for increasing amounts of iron, up to 10 moles per cent Fe<sub>2</sub>O<sub>3</sub>; these results (Fig. 1) suggest a limiting composition 3 CaO.(Al<sub>0.95</sub>Fe<sub>0.05</sub>)<sub>2</sub>O<sub>3</sub> for the solid solutions prepared at 1,310° C.

These results do not necessarily imply that the limiting composition obtained at 1,389° C by Schlaudt and Roy is in error, but, most probably, the 'low' temperature (1,200–1,350° C) region of their phase equilibrium diagram needs some revision.

By applying the same technique to the isomorphic replacement of iron by aluminium in 2 CaO.Fe<sub>2</sub>O<sub>3</sub>, the

Fig. 1. 2θ diffraction angles of the lines 12.8.4, 12.4.0 and 8.8.0 as a function of  $\text{Fe}_2\text{O}_3$  content in the system  $3\text{CaO}(\text{Al},\text{Fe})_2\text{O}_3$ .

limiting composition of the solid solution is found to be  $2\text{CaO}(\text{Fe}_{0.75}\text{Al}_{0.25})_2\text{O}_3$ , in perfect agreement with previous data of Malguori and Cirilli<sup>2</sup>, but significantly different from the  $2\text{CaO}(\text{Fe}_{0.25}\text{Al}_{0.75})_2\text{O}_3$  limit proposed by Toropov and Boikova<sup>3</sup>.

These results strongly suggest that the phases  $3\text{CaO} \cdot \text{Al}_2\text{O}_3$  and  $2\text{CaO} \cdot (\text{Al}_{0.75}\text{Fe}_{0.25})_2\text{O}_3$  (the so-called  $\text{C}_3\text{A}$  and  $\text{C}_4\text{AF}$  phases in the chemistry of cements) cannot co-exist as such (as it is admitted in the calculation of the potential mineralogical composition of clinkers) since some iron is liable to pass from the  $\text{C}_4\text{AF}$  phase into the  $\text{C}_3\text{A}$  phase—this being counterbalanced by the transfer of an equivalent amount of alumina from  $\text{C}_3\text{A}$  to  $\text{C}_4\text{AF}$ .

Intimate mixtures of  $\text{C}_3\text{A}$  and  $\text{C}_4\text{AF}$  in various ratios were fired at  $1,300^\circ\text{C}$ , then air quenched, and the resulting phases investigated by X-ray diffraction and infra-red absorption spectra. The composition of these phases (as deduced from the 2θ values) is summarized in Table 1.

Table 1. CHANGES IN THE COMPOSITION OF  $\text{C}_4\text{AF}$ - $\text{C}_3\text{A}$  MIXTURES AFTER FIRING AT  $1,300^\circ\text{C}$

Initial composition of the mixture (in moles)		Composition of the solid solutions obtained after firing	
$\text{C}_4\text{AF}$	$\text{C}_3\text{A}$	$\text{C}_4\text{AF}$	$\text{C}_3\text{A}$
0.25	0.75	$\text{C}_4\text{AF}_{0.1-0.2}\text{Fe}_{0.9-0.8}$	$\text{C}_3\text{A}_{0.9-0.8}\text{Fe}_{0.1-0.2}$
0.50	0.50	$\text{C}_4\text{AF}_{0.1-0.2}\text{Fe}_{0.8-0.7}$	$\text{C}_3\text{A}_{0.8-0.7}\text{Fe}_{0.2-0.3}$
0.75	0.25	$\text{C}_4\text{AF}_{0.1-0.2}\text{Fe}_{0.7-0.6}$	$\text{C}_3\text{A}_{0.7-0.6}\text{Fe}_{0.3-0.4}$

The aluminium-iron exchange between the 2 phases  $\text{C}_3\text{A}$  and  $\text{C}_4\text{AF}$  is thus definitely proved. A further, qualitative checking of such exchanges is also given by infra-red absorption investigations, the infra-red absorption spectrum of a simple mechanical mixture of  $\text{C}_3\text{A}$  and  $\text{C}_4\text{AF}$  being fairly different from the spectrum of a mixture of the same gross composition fired at  $1,300^\circ\text{C}$ .

It is also worth mentioning that the high-angle diffraction lines and the infra-red absorption bands of such mixtures are significantly broadened after firing at  $1,300^\circ\text{C}$ : this suggests an imperfect crystallization state. In some of the mixtures investigated, a further firing at

$1,340^\circ\text{C}$  (followed by air quenching) brings out such a broadening of the high-angle diffraction lines that precise position measurements are impossible.

This bad crystallization state, together with the occurrence of  $\text{C}_3(\text{A},\text{F})$  solid solutions containing significant amounts of iron, have important implications in the chemistry of cements, since both factors are likely to affect the chemical nature of the hydrated phases, and the kinetics of the hydration phenomena.

This work was supported by the Institut pour l'Encouragement de la Recherche Scientifique dans l'Industrie et l'Agriculture (I.R.S.I.A.) and by the Centre National de Recherches Scientifiques et Techniques pour l'Industrie Cimentière.

## BIOPHYSICS

### Ribonucleic Acid Synthesis in Synchronously Dividing Populations of HeLa Cells

A NUMBER of investigations directed towards the description of the events occurring during the reproductive cycle of the mammalian cells have been made in randomly dividing cell populations. For example, the time-course of synthesis of DNA has been elucidated in several systems by use of microspectrophotometric or autoradiographic techniques<sup>1-3</sup>. However, for investigations in which it is difficult to identify the stage of a cell in the mitotic cycle, synchronously dividing populations are of value. Recently, we were able to obtain large populations of mitotically synchronized HeLa S-3 cells by preferential detachment of cells in mitosis from nearly confluent monolayers growing in very low calcium medium. We report here some of our observations on the rate of RNA synthesis in synchronized HeLa cells during one division cycle.

The technique of obtaining synchronized populations is a modification of that of Robbins and Marcus<sup>4</sup>. HeLa S-3 cells were grown in monolayers on a flat glass surface in French square bottles using Eagle's medium supplemented with 10 per cent calf serum. Three to four day stock cultures were trypsinized and  $7.0 \times 10^5$  cells were transferred to each of twelve 32-oz. bottles (surface area  $97\text{ cm}^2$ ). After cells were grown in regular Eagle's medium supplemented with 10 per cent calf serum for three days, growth medium was removed from the bottles, and replaced with low calcium medium. Cells were incubated at  $37^\circ\text{C}$  for 20 h. Three hours before use, the bottles were vigorously shaken and washed with the low calcium medium to eliminate any floating and dead cells. (This procedure was found to be necessary in order to eliminate any interphase cells at the time of collection of the mitotic cells.) At collection time the bottle was grasped by the neck and shoulders, held at eye-level horizontally, and inverted as quickly as possible so that the medium passed rapidly over the cells. The bottle was quickly opened and the cell suspension was poured into a conical centrifuge tube. After centrifugation, the cells were plated in 60-mm plastic Petri dishes in 4 ml. of normal growth medium. All procedures were carried out at  $37^\circ\text{C}$  in a warm room, except for the centrifugation and plating procedures. For the examination of RNA and DNA synthesis, the extent of incorporation of tritiated uridine and tritiated thymidine into RNA and DNA was considered a measure of RNA and DNA synthesis respectively. Cells were incubated for 15 min in media containing the radioactive compounds mentioned here, then washed three times with

saline and removed by trypsinization. 1 ml. of the trypsinized cells was used to count the number of cells per plate by the use of a Coulter counter model B; the rest of the samples were centrifuged and frozen. To determine the tritiated thymidine incorporation into DNA, cells were washed three times in cold 5 per cent trichloroacetic acid, washed once in 80 per cent ethanol, and dissolved in 0.2 ml. of 0.2 N sodium hydroxide. The final sample was counted in a liquid scintillation counter. For the tritiated uridine incorporation into RNA, the separation of RNA from DNA radioactivity was achieved by the method of Kahn<sup>4</sup>. The filters were transferred to counting vials and the radioactivity was counted by the liquid scintillation counter.

Fig. 1. Growth of mitotically synchronized HeLa S-3 cells. Mitotic cells were collected at 37° C and equal numbers of cells were plated down in plastic Petri dishes. At various intervals, cells were trypsinized and changes in cell number were determined by a Coulter counter model B.

Fig. 1 shows the increase in cell number per plate, after plating down the collected cells. Cytological examinations were made every time the cells were collected. More than 90 per cent of the collected cells were visibly in mitosis. The fraction of cells dividing during the first 20 h constituted less than 10 per cent of the population, after which 85–95 per cent underwent division during a 9–10 h period. In order to determine the degree of the synchrony, we used the index of synchrony ( $F$ ) proposed by Blumenthal and Zaler<sup>5</sup>:

$$F = \frac{N_2}{N_1} - e^{kt}$$

where  $N_1$  is the number of cells at time  $t_1$ ;  $N_2$  is the number of cells at time  $t_2$ ;  $t$  is the time-interval  $t_2 - t_1$ ; and  $k$  is 0.693/doubling time. For the data of Fig. 1, the value for  $F$  is 0.72.

To investigate the timing of RNA synthesis, we determined the rates of incorporation of tritiated uridine into RNA throughout the mitotic cycle (Fig. 2). As a comparison of reference, the rate of the DNA synthesis determined by the extent of the incorporation of tritiated thymidine was made. One sharp peak in the rate of DNA synthesis occurred at 16 h. The rate of RNA synthesis showed two maxima and minima; the maxima appeared at 15 and 20 h; the minima at 18 and 24 h.

The results of the foregoing experiment demonstrate that the rate of tritiated uridine incorporation is not uniform throughout the mitotic cycle but decreases during the mitosis. This finding is, at least qualitatively, in agreement with the recent report by Mittermayer *et al.* in *Physarum polycephalum*<sup>6</sup>, in which two peaks of RNA synthesis, during the mitotic cycle, were shown. Reiter and Littlefield<sup>7</sup>, using partially synchronized mouse fibroblasts, obtained by the use of 5-fluorodeoxyuridine, showed that the synthesis of nuclear RNA, as judged by the rates of incorporation of hypoxanthine-<sup>14</sup>C, decreased somewhat during the period of DNA synthesis, increased as the latter slowed, and remained active before and after mitosis. The use of a metabolic inhibitor, however,

Fig. 2. The rates of incorporation of tritiated uridine and thymidine into RNA and DNA respectively during synchronized growth of HeLa S-3 cells. Approximately  $10^4$  cells per plate were inoculated in regular growth media containing either tritiated uridine (3  $\mu$ Ci/ml, spec. act. 2.0 c/mmole) for RNA synthesis or tritiated thymidine (0.5  $\mu$ Ci/ml, spec. act. 1.9 c/mmole) for DNA synthesis for 15 min. ●, Tritiated uridine; ○, tritiated thymidine.

for study of normal relationships between intracellular metabolic events occurring during the mitotic cycle is limited, as severe temporal distortions may result by the chemical stresses imposed. Our technique of obtaining synchronized population imposes minimal stress on the system and, as demonstrated here, caused no distortion of the normal pattern of DNA synthesis.

At present we are attempting to correlate the cyclic variations of RNA synthesis with RNA polymerase activity in this system.

### Inhibition of Photo-inactivation of Taka-amylase A by Halogen Ions

RIBOFLAVIN is known as a favourable sensitizer in various photochemical reactions such as photo-oxidation of vitamins<sup>1</sup>, plant growth hormone<sup>2-4</sup> and deoxyribonucleic acid<sup>5</sup>, and photo-inactivation of amylase<sup>6,7,12</sup>.

In the presence of oxygen, riboflavin is decomposed by visible light to lumiflavin<sup>8-10</sup> or humichrome and ribose side chain<sup>11</sup>. Lumiflavin is finally transformed to stable humichrome.

In the presence of riboflavin, taka-amylase A (isolated<sup>13</sup> from taka-diastase 'Sankyo') is rapidly inactivated by

Fig. 1. Effect of halogen ions on initial velocity of photo-inactivation of taka-amylase A and fluorescence yield of riboflavin. Concentration of amylase, 0.005 per cent; concentration of riboflavin,  $8.8 \times 10^{-4}$  M; concentration of halides, 0.05 M; exciting light, light absorbed by 445 mμ-band of riboflavin; pH, 5.6 (acetate buffer); temperature, 20° C.  $R_0$ , initial velocity of photo-inactivation in the absence of halide;  $\eta_0$ , fluorescence yield of riboflavin in the presence of halide;  $\eta$ , fluorescence yield in the absence of halide; curves 1 and 3,  $R/R_0$  and  $\eta/\eta_0$  in the presence of potassium halides; curves 2 and 4,  $R/R_0$  and  $\eta/\eta_0$  in the presence of calcium halides.

Fig. 2. Dependence of initial velocity of photo-inactivation and fluorescence yield on concentration of potassium iodide. Concentration of amylase, 0.005 per cent; concentration of riboflavin,  $8.8 \times 10^{-4}$  M; pH, 5.6 (acetate buffer); temperature, 20° C; exciting light, light absorbed by 445 mμ-band of riboflavin; curve 1,  $R/R_0$ ; curve 2,  $\eta/\eta_0$ .

the visible light absorbed by riboflavin or its derivatives if oxygen is present. The inactivation is caused by the oxidation of amino-acid residues<sup>12</sup>. The addition of potassium or calcium halide to taka-amylase A solution (pH 5.6) containing riboflavin inhibits efficiently the photo-inactivation. The presence of these halides does not affect the activity of taka-amylase A under the dark condition. The ratio of initial velocity ( $R$ ) of photo-inactivation in the presence of halide to that ( $R_0$ ) in the absence of halide is shown in Fig. 1. The velocity of photo-inactivation decreases with the increase of the atomic number of the halogen atom. The order of effectiveness of the halogen atoms is  $I > Br > Cl$ .

The effect of halogen ions on fluorescence yield of riboflavin in the same system is also shown in Fig. 1. The fluorescence yield decreases with the increase of the atomic number of halogen atom. Fig. 2 shows the dependence of fluorescence yield of riboflavin and initial velocity of photo-inactivation on the concentration of potassium iodide. The velocity of photo-inactivation begins to decrease at an extremely low concentration of potassium iodide, of the order of  $10^{-7}$  M, while the fluorescence begins to be quenched at much higher concentration of potassium iodide, the order of  $10^{-5}$  M. These indicate that the reactive species of riboflavin is the triplet molecule and that the inhibition of photo-inactivation is caused by the quenching of the triplet state of riboflavin by halogen ions.

This consideration is also supported by the strong quenching of orange phosphorescence by the presence of

iodine ion even below  $10^{-4}$  M, which runs parallel to the inhibition of photo-inactivation.

Riboflavin or its derivatives in the metastable triplet state may form a complex with oxygen in the triplet ground state. According to the spin conservation law, singlet, triplet and quintet states are allowed for this complex. The singlet complex dissociates into singlet dye and singlet oxygen (production of reactive oxygen) and the triplet one into singlet dye and triplet oxygen (quenching of triplet state of dye). The metastable and chemically reactive singlet oxygen may oxidize amino-acid residues directly or react with water to produce hydrogen peroxide which may oxidize them. In the presence of halogen ions, the pure triplet state can be mixed with an appropriate pure singlet state as the result of a collisional perturbation of spin-orbital coupling<sup>14,15</sup> in the  $\pi$ -electron orbitals of riboflavin, by halogen ions. The transition probability between singlet and triplet is greatly enhanced.

Perturbation occurs by the overlapping of the  $\pi$ -orbital of riboflavin with the halogen  $p$ -orbitals during the collision. The enhancement of the singlet-triplet absorption band of  $\alpha$ -chloro-naphthalene in intensity by ethyl iodide has been found by Kasha<sup>16</sup> and discussed in terms of the collisional perturbation of spin-orbit coupling. The collisional perturbation gives rise to the enhancement of the dissipation of excitation energy by radiationless transition from excited singlet to ground state via triplet state. From the dependencies of photo-inactivation and fluorescence on halogen ion concentration, it is considered that the collisional perturbation of spin-orbit coupling by halogen ion, in the present case, increases the radiationless transition probability from triplet to singlet state more efficiently than it does that from excited singlet to triplet state, as the result of the mutual relation among the various processes of radiative and non-radiative transitions and heat activation. This results in the shortening of the life-time of the triplet state of riboflavin responsible for the photosensitizing action. The matrix element of the spin-orbital operator included in the singlet-triplet mixing coefficient contains the atomic number as a parameter<sup>14</sup>. For this reason, it is considered that the effectiveness of the halogen atom for the inhibition of photo-inactivation increases with the increase of the atomic number of the halide atoms.

However, we cannot completely neglect the possibility of formation of an unstable charge-transfer complex<sup>16</sup> of riboflavin with halogen ion, especially iodine ion. The fluorescence and phosphorescence states may be deactivated by transfer of charge from halogen ion to riboflavin. This kind of quenching also seems to take part in the inhibition of photo-inactivation to some extent. Further details will be published in a future paper.

## BIOCHEMISTRY

## Simultaneous Chromatographic Separation and Infra-red Sample Preparation of Indole Acids

In attempting to identify trace amounts of metabolites from biological fluids, the use of one of the most powerful tools of organic chemical analysis, infra-red spectroscopy, presents technical difficulties. The two major ones are: (a) a sample preparation technique for the characteristically polar compounds, and (b) sufficient purity to allow a resolvable spectrum.

Having become involved in the problem of the identification of microgram amounts of indole acids in urine<sup>1</sup>, it was found that conventional chromatography, elution, and KBr micro-pellet sample preparation was frequently accompanied by contamination from cellulose particles and complexes of solvent and cellulose in spite of the use of rather rigorous techniques<sup>2,3</sup>. It was at this time that the work of Sloan<sup>4</sup>, demonstrating the infra-red transparency of membrane filters ('Millipore TH') and their use in the infra-red examination of hydraulic fluids and condensates from tobacco smoke was brought to our attention. About the same time Thomas and Dwyer<sup>5</sup> reported the use of this membrane in the collection and infra-red examination of gas chromatographic effluents. Although both these papers speculated on the use of this material for partition chromatography, there have been no reports of its use in this way. One of the major limitations of the use of this polymer is its solubility in most polar solvents<sup>6</sup>. Another is that with careful compensation using a matched blank piece in a double-beam infra-red system, the strong absorption regions (Fig. 1) of 6.1, 7.8, 9.4 and 11.9 permit too little energy through to allow analysis in these areas. Following the trial of several solvent combinations, it was found that isopropanol-ammonia-water (8:1:1) and butanol-acetic acid-water (12:3:5) (good solvent systems for the indole acids) leave the membrane intact. It should be noted that these two solvent systems are good for amino-acid separations as well. In addition, the compensated membrane has 'windows' in the N—H, carbonyl, and aromatic C—H areas of interest for identification of indole acids.

Fig. 1. An infra-red spectrum of the membrane against air

Fig. 2. Two infra-red spectra. 'Blank' is an empty area of the chromatogram against a blank sheet of membrane. 'IAA' is an area of the chromatogram containing indolyl-3-acetic acid against a blank sheet of membrane

Fig. 3. An infra-red spectrum of the  $\nu$ N—H (A), carbonyl (B) and aromatic C—H (C) with a 5  $\times$  increase in IAA concentration

Following spotting, 19 mm by 41 m strips of the membrane were run uni-dimensionally in a conventional ascending chromatography apparatus. An amount of indole acids (indolyl-3-acetic acid, indolyl-3-carboxylic acid, 5-hydroxy-indolyl-3-acetic acid, and tryptophan) equivalent to that contained in 15 c.c. of urine was used. Following chromatography, the solvent was removed by air and/or oven-drying and serial spectra on each chromatogram were run against a blank membrane every 0.4 cm from the origin to the solvent front. After infra-red examination, the membranes were sprayed lightly with acidic alcoholic solutions of *p*-dimethylaminobenzaldehyde or *p*-dimethylaminocinnamaldehyde to locate the substances.

Fig. 2 is a rather typical spectrum that was observed using this technique, with small samples (1 micromole) and a low-resolution instrument (Beckman 'I.R.5'). The 'blank' is the spectrum seen using an area of the chromatogram without sample against a blank sheet of membrane. The 'IAA' is the spectrum of the IAA area of the chromatogram against the blank. Note that the match is slightly undercompensated in favour of the blank so that the strong absorption peaks (\*) of the membrane are reversed (up) leaving the chromatogram's peaks more clearly seen in the conventional down direction. Another feature of the IAA spectrum is the bathochromic shift of  $\nu$ N—H (A) and carbonyl (B) peaks when compared with those seen in KBr pellets. In addition, the  $\nu$ N—H, characteristically sharp, looks 'bottomed out' like the  $\nu$ O—H seen in concentrated solutions due to hydrogen bonding. These peaks

are of importance in the study of indole acids in that they shift characteristically with inductive effects of substituents at various positions<sup>7</sup> and thus are an aid in identification. In order to establish whether the shifts seen in the chromatographic substances were due to intermolecular hydrogen bonding between indole acid molecules or the indole acid and the membrane, increasing amounts of material were placed on the chromatogram (beyond the amounts in which spot size is linearly related to amount) so as to increase the ratio of indole-indole to indole-membrane interactions. Fig. 3 shows both the sharpening of the  $\nu$ N—H (A) and aromatic C—H (C) as well as a shift to lower wave-length of  $\nu$ N—H and the carbonyl (B) peaks consistent with a decrease in hydrogen bonding when the amount is increased to 5 micromoles. This suggests that, with low concentrations, there are bonding interactions of the chromatographed substances with the cellulose ester molecules of the membrane. With a low-resolution instrument, this effect makes the use of  $\nu$ N—H less helpful in discriminating between indolyl-3-acetic acid and indolyl-3-carboxylic acid; the bathochromic shift of the latter becomes less differentiable due to the hydrogen-bonding induced comparable shift in indolyl-3-acetic acid. Having taken this effect into account, however, it was possible to discriminate among these indole acids spectroscopically.

A systematic attempt is being made to improve the separations by systematically varying solvent and solvent ratios. It appears that this method may be quite useful in the application of infra-red techniques to the identification of trace substances from biological fluids.

I thank Mr. J. Dwyer and the Millipore Corporation for the 'Millipore TH' membranes, and M. H. Sloan for advice. The work was supported by California D.M.H. grant 64-2-22-1 and by the Scottish Rite Fund for Research in Schizophrenia.

### Melanocyte-stimulating Hormone Activity of Synthetic MSH and ACTH Peptides, *in vivo* and *in vitro*

SIMULTANEOUSLY performed *in vivo* and *in vitro* determinations of the melanocyte-stimulating hormone (MSH) activity of a large number of synthetic MSH and ACTH peptides have not been reported previously. The work recorded here compares by both methods the MSH activity of 10 stereoisomeric pentapeptide fragments of MSH and 8 synthetic peptides related to ACTH. The MSH activity of most of the stereoisomers appeared greater *in vivo* than *in vitro*. When these compounds were assayed at various time intervals, some of the pentapeptides revealed differences which may help partially to explain this discrepancy in activity between the two methods. These differences may also help in understanding the alterations of  $\alpha$ -MSH induced by sodium hydroxide<sup>1,2</sup>. In addition, preliminary studies were performed on the inhibitory properties of the stereoisomers.

For the *in vivo* assay, solutions were injected into the dorsal lymph sac of hypophysectomized *Rana pipiens*. Melanin granule dispersal (darkening) was measured in the interdigital web of the foot, as previously described<sup>3</sup>. Doses were given so as to bracket the melanocyte index of 3.0. At the same time, darkening of isolated pieces of frog skin was determined in the *in vitro* assay by reflected light<sup>4,5</sup>. At least 3 hypophysectomized frogs and 2 frog skins were utilized at each of 2 dose levels. For measurement of the synthetic peptides *in vivo*, a mean of 5.2 frogs was used at each of 2.9 doses; for *in vitro* assays, a mean of 4.1 skins was used at 2.5 doses. The 'unit' of activity used in this communication was defined by Shizume *et al.*<sup>6</sup>.

The mean estimates of MSH potency, with 95 per cent confidence limits, are given in Table 1. The *in vivo* assay method gave higher activities for most of the MSH pentapeptides than did the *in vitro* method.

*In vivo*, the 30-min reading of the melanocyte index approximated the maximum degree of melanin granule dispersal. This darkening was significantly diminished ( $P < 0.01$ ) at the final 1-h reading with MSH standard, pure  $\alpha$ -MSH, and the 7 ACTH peptides tested. The darkening was not decreased at 1 h, however, with D-His-D-Phe-L-Arg-L-Try-Gly, L-His-D-Phe-L-Arg-L-Try-Gly, and some of the other MSH pentapeptides tested only in a few frogs before the supplies were exhausted. The same difference in behaviour between stereoisomers and MSH standard when injected into the dorsal lymph sac was observed when the substances were injected directly into the aortic trunk. Changing the pH of the solutions from 6.7 to 2.1, moreover, did not alter this finding.

*In vivo*, 6 ACTH compounds as well as the D-His-D-Phe-L-Arg-L-Try-Gly and the L-His-D-Phe-L-Arg-L-Try-Gly pentapeptides were read every 30 min for 2 h. Each stereoisomer required a significantly ( $P < 0.01$ ) longer time (approximately 2 h versus 1.5 h) to reach its maximum effect than did MSH standard, pure  $\alpha$ -MSH, or any of the ACTH peptides.

Thus, both the *in vivo* and the *in vitro* behaviour of D-His-D-Phe-L-Arg-L-Try-Gly contributed to the discrepancy in MSH values observed for this compound between the two methods. Although L-His-D-Phe-L-Arg-L-Try-Gly manifested similar differences in assay behaviour, it did not reveal a similar discrepancy in MSH activity. No significant deviation from the behaviour of the standard in either assay was noted for any of the ACTH compounds tested.

The differences in darkening shown by some of the stereoisomers, when measured at various time intervals, were similar to the phenomena of 'prolongation' and 'retardation' seen after sodium hydroxide treatment of  $\alpha$ -MSH<sup>1,2</sup>. In an attempt to explain this action of dilute alkali, Lee and Buettner-Janusch<sup>3</sup> obtained evidence that sodium hydroxide caused racemization of 5 of the 13 amino-acids in natural  $\alpha$ -MSH. Of these 5 amino-acids, 4 were present in the synthetic stereoisomeric peptides tested in the assays reported here. The results reported here, therefore, lend support to the suggestion<sup>1,2</sup> that alkali modification of  $\alpha$ -MSH involves racemization of some of its amino-acids.

Inhibitory properties of the MSH pentapeptides were tested only in a preliminary way, due to a limited supply of the compounds. *In vitro*, none of the 10 MSH peptides inhibited the action of MSH standard when given 1 h earlier at a concentration of 1.5  $\mu$ g/ml. However, 83  $\mu$ g/ml. of D-His-D-Phe-D-Arg-D-Try-Gly did result in inhibition *in vitro*, as has been reported<sup>4</sup>. *In vivo*, 600  $\mu$ g of this pentapeptide injected 0.5 h to 2 h before the MSH standard did not cause inhibition. A single dose of 100  $\mu$ g failed to lighten a frog previously darkened by destruction of the hypothalamus.

We thank Dr. D. F. Elliott of Ciba, Ltd., for supplying the synthetic peptides related to ACTH, which were prepared at Ciba, Basle; Mrs. Jane Hull, for

her assistance; and Dr. Emmanuel H. Breiler for his advice.

## N-Acetylmannosamine Digestion by Human Oral Bacteria

LEACH<sup>1</sup> showed that *N*-acetylneuraminic acid was rapidly metabolized by human saliva and ascribed this to the presence of an inducible aldolase produced by contaminating micro-organisms since such destruction was prevented by the addition of 'Ledermycin' or by heating the saliva in boiling water. This appears to be the second step in a process whereby salivary mucoproteins having *N*-acetylneuraminic acid residues as their non-reducing end groups act as inducer molecules to oral bacteria, producing first a neuraminidase and later an aldolase which cleaves the *N*-acetylneuraminic acid liberated by the neuraminidase into *N*-acetylmannosamine and pyruvic acid. Such a sequence has been found by us<sup>2</sup> to occur when  $\alpha_1$ -glycoprotein, which is present in sputum, is used as an inducer molecule in cultures of *Klebsiella aerogenes*. We wish to report on the third step whereby *N*-acetylmannosamine itself is digested.

Fresh saliva samples (0.5 ml.) were incubated with sterile aliquots of *N*-acetylmannosamine (100  $\gamma$  in 0.1 ml.) at 37° for 2 h, dialysed against water (100 volumes) at 4° and the dialysate freeze-dried before assay with the Morgan-Ellson reagents<sup>3</sup>. From a random group of healthy individuals including smokers and non-smokers, the amounts of *N*-acetylmannosamine remaining were with A, 77  $\mu$ g; B, 34  $\mu$ g; H, 95  $\mu$ g; M, 90  $\mu$ g; P, 84  $\mu$ g and W, 51  $\mu$ g. In a further incubation of saliva from B, only 40, 30 and 10 per cent of the original *N*-acetylmannosamine was left after 1, 2 and 4 h respectively. When saliva from B was assayed with incubation for 1 h before and after a mouth-wash, first with 'Dettolin' (2.5 ml./70 ml. water) and then with hydrogen peroxide (5 ml. 20 vol./70 ml. water), it was found that the first mouth-wash produced arrest of *N*-acetylmannosamine digestion (73  $\mu$ g remaining) compared with saliva before washing (45  $\mu$ g remaining), but this was not increased by the second mouth-wash (73  $\mu$ g remaining).

When glucose (1 mg) was included in the incubation mixture in addition to *N*-acetylmannosamine (100  $\mu$ g), digestion of the latter was again arrested: B with glucose, 63  $\mu$ g; B without glucose, 41  $\mu$ g (2 h incubation); W with glucose, 90  $\mu$ g (2 h), 60  $\mu$ g (4 h); W without glucose, 11  $\mu$ g (4 h). Glucose is widely effective in inhibiting enzyme induction in bacteria.

The micro-organisms responsible for *N*-acetylmannosamine digestion in the saliva of B and W differed in their sensitivity to a range of antibiotics. Each antibiotic (5 mg) was incubated with the saliva for 1 h at 37° before further incubation with *N*-acetylmannosamine (100  $\mu$ g) for 4 h. The amount ( $\mu$ g) remaining with B saliva was with erythromycin, 99; tetracycline, 76; streptomycin, 68; kanamycin, 51; methymycin, 50; without any antibiotic, 37. On one occasion with W saliva the amount ( $\mu$ g) remaining was, with tetracycline, 93; without any antibiotic, 65; while later with another sample no completely effective arrest was shown with streptomycin, 53; erythromycin, 45; methymycin, 26; paromomycin, 25; kanamycin, 22, compared with a control without antibiotic, 14.

Further evidence that the agent responsible for *N*-acetylmannosamine digestion was an enzyme induced in a micro-organism was obtained by comparing the amounts remaining after autoclaving salivas B, 99 W, 100, after Seitz filtration of salivas B, 97 W, 99, compared with no previous treatment of B, 49 W, 64  $\mu$ g.

## Kinetics of Cyclic Adenosine Monophosphate Changes in Rat Heart following Epinephrine Administration

ALTHOUGH it has become generally accepted<sup>1</sup> that epinephrine causes glycogenolysis in cardiac muscle by a series of enzymatic reactions involving the formation of cyclic AMP, activation of phosphorylase *b* kinase, and finally conversion of phosphorylase *b* to the active *a* form, direct evidence in favour of this mechanism in the intact heart is so far not conclusive<sup>2</sup>. Furthermore, a possible relation between cyclic AMP and the inotropic effect of catecholamines is also tentative.

In view of the recent findings<sup>3,4</sup> that the inotropic response of the rat heart to epinephrine precedes the glycogenolytic effect, it is clearly of great importance to determine the kinetics of the cyclic AMP changes in relation to the elevation of the contractile force and phosphorylase *a* levels in order to gain a deeper understanding of the mechanisms involved.

Hearts were taken from male, fed rats of Wistar strain (220–260 g) and perfused as described by Williamson<sup>5</sup>. Cyclic AMP in 500-mg samples of frozen heart powder was extracted and assayed by the method of Posner *et al.*<sup>6</sup>. Cyclic AMP phosphodiesterase was prepared according to Butcher and Sutherland<sup>7</sup>. Other analytical procedures were similar to those used by Williamson<sup>5,8</sup>.

Fig. 1 compares the change in the level of cyclic AMP with that of the total phosphorylase in the *a* form, and that of the contractile force, following the addition of a single dose of 1  $\mu$ g epinephrine. The contractile force increased to a maximum after 10–12 sec with a half-time of 3.5 sec, and afterwards decreased to a value 30 per cent above the initial at the end of 30 sec. More extensive recordings of the contractile force reported elsewhere<sup>3,4</sup> have shown that the pattern of the contractile force depicted in Fig. 1 is characteristic of a single large dose of epinephrine, and that the force increases again after 30 sec, reaching a plateau 60–70 per cent above the control after about 90 sec. This level is maintained for as long as 10 min. Cyclic AMP levels increased in a manner similar to the force curve ( $t_{1/2}$  = 3.5 sec), and also paralleled it during the declining phase from 15 to 30 sec. At the end

of 30 sec, the cyclic AMP levels were three times higher than the controls. Also seen from Fig. 1, phosphorylase *a* increased from 12 to 65 per cent of the total phosphorylase activity but with a lag of about 2 sec, and the time for a half-maximal increase was 7.5 sec.

The initial cyclic AMP peak may represent an overshoot reaction of the adenylate cyclase system as it is first exposed to epinephrine, or merely a temporary imbalance between an accelerated rate of production and degradation before a new steady state is established.

Fig. 2 shows the results of an experiment in which the hearts were perfused continuously with fluid containing 0.05  $\mu\text{g/ml}$  epinephrine. With this concentration of epinephrine, the force increased to a maximum after 15–18 sec ( $t_{\frac{1}{2}} = 3$  sec) and remained approximately constant for the 2-min duration of the experiment. Cyclic AMP levels increased monotonically from the onset of the augmentation of the contractile force to reach a maximum after about 14 sec ( $t_{\frac{1}{2}} = 5$  sec) and thereafter decreased, in much the same manner as in Fig. 1, to a new steady-state level considerably higher than the controls.

Fig. 2 also shows the changes in the levels of glucose-6-P and fructose-1,6-diP in the same experiment. Glycogenolysis in response to epinephrine produced an increase in the levels of these intermediates after a short lag period. Glucose-6-P increased by 80 per cent to give a broad maximum after 30–40 sec, while fructose-1,6-diP increased three-fold, to reach a sharp maximum after 25 sec and approached a new steady-state level in an oscillatory manner. Fructose-6-P (not shown) followed a pattern similar to glucose-6-P, and the mean ratio of glucose-6-P to fructose-6-P was 5:3.

The work recorded here establishes on a kinetic basis that epinephrine causes a rapid increase of cyclic AMP in the heart, followed by an increase in the level of phosphorylase *a*. Demonstration of glycogen disappearance within the first minute of epinephrine administration to the isolated rat heart has been reported previously<sup>4</sup>. These investigations, therefore, provide the necessary link between the work of Murad *et al.*<sup>6</sup> on particular preparations of heart muscle, and the intact organ, and lend

Fig. 1. Effect of epinephrine on the contractile force, cyclic AMP content and percentage of the total phosphorylase as phosphorylase *a* in the rat heart. Hearts were perfused at 37° with non-recirculating medium containing 10 mM glucose. Two determinations for cyclic AMP were made on each sample, once with an aliquot of extract treated with trypsin and trypsin inhibitor<sup>7</sup>, and once with a similar extract after a further incubation for 3 h at 80° with 2 units of cyclic AMP phosphodiesterase. The latter treatment decreased the apparent cyclic AMP to a constant level in all extracts, equivalent to 2.0 nmol/g dry wt. This mean figure was subtracted from each value obtained in the first assay to give the values shown. Recoveries of cyclic AMP added to extracts were essentially quantitative.

Fig. 2. Effect of epinephrine on the contractile force and the contents of cyclic AMP, glucose-6-P and fructose-1,6-diP in rat hearts perfused continuously at 37° with medium containing 10 mM glucose,  $5 \times 10^{-4}$  M EDTA and 0.05  $\mu\text{g/ml}$  epinephrine. The residual apparent cyclic AMP content after diesterase treatment was 2.8 nmol/g dry wt., and the values were corrected as before.

support to the prevalent hypothesis<sup>1</sup> concerning the mechanism of phosphorylase activation in the heart by epinephrine.

It should perhaps be stressed that the response of cyclic AMP following epinephrine administration is fast and short-lived. The finding of Hammermeister *et al.*<sup>2</sup> that there was no significant change in the level of cyclic AMP 30 sec after epinephrine stimulation is thus explainable in light of the results recorded here.

The short time-lag between the increase of contractile force and cyclic AMP on one hand, and phosphorylase *a* and glucose-6-P on the other hand, indicates that energy produced from glycogen breakdown<sup>10</sup> or the level of glucose-6-P<sup>11</sup> are not involved in the inotropic response. The delay between the stimulation of cyclic AMP production and the conversion of phosphorylase *b* to *a* probably reflects a delay either in the activation of phosphorylase *b* kinase or in the phosphorylation of the serine residues of phosphorylase *b* in its conversion to the *a* form<sup>12</sup>. Danforth and Helmreich<sup>13</sup> have also observed a lag period between the onset of electrical stimulation and the appearance of phosphorylase *a* in isolated frog sartorii, and on the basis of *in vitro* studies, these authors attributed the lag to the time required to activate the phosphorylase *b* kinase reaction.

The fact that cyclic AMP levels in the heart increased more than two-fold within 1.5 sec of the onset of the inotropic response provides kinetic evidence in favour of its also being a mediator in the events leading to the increased force of contraction. The lack of correspondence between the level of cyclic AMP and the contractile force after the peak of cyclic AMP response, however, suggests that it may have a trigger role, possibly by allowing a greater influx of calcium per beat or by interference with the removal of ionized calcium by the endoplasmic reticulum<sup>14,15</sup>.

It has been shown elsewhere<sup>16</sup> that during epinephrine-stimulated glycogenolysis in the perfused rat heart phosphofructokinase is activated by an increase in the levels of inorganic phosphate, AMP and ADP. The kinetics of the changes in the levels of cyclic AMP in relation to those of fructose-1,6-diP shown in Fig. 2 suggest that this nucleotide plays a relatively unimportant part in the activation of phosphofructokinase *in vivo*.

### Chemical Structure and Biological Activity on *m*- and *p*-Disubstituted Derivatives of Benzene

In an earlier paper on this topic<sup>1</sup> we proposed a four-parameter equation (1), which expresses the quantitative relationship between the structure of *p*-disubstituted derivatives of benzene and the magnitude of their biological activity, for example intravenous  $LD_{50}$ . This report presents our results on a group of compounds of the type

$NO_2$ ,  $NH_2$ . The series includes all possible combinations of groups  $X$  and  $Y$ , with the exception of three substances which were not soluble enough even in 20 per cent aqueous polyvinylpyrrolidone solution to make  $LD_{50}$  measurements possible. The experimental results fitted equation (1):

$$\log \frac{[LD_{50}]_{HH}}{[LD_{50}]_{XY}} = b_X + b_Y + e_X e_Y \quad (1)$$

Constants  $b_X$  and  $e_X$  were obtained by statistical treatment of experimental data under the presumption of the validity of equation (1). Fig. 1 shows the correlation obtained; the values of the substituent constants  $b_X$  and  $e_X$  are given in Table 1.

Table 1

	$NO_2$	Cl	OH	$CH_3$	H	$NH_2$
$b_X$	0.601	-0.248	0.260	0.149	0.004	-0.015
$e_X$	0.90	-0.49	-0.13	-0.23	-0.06	-0.41

Table 2

	$NO_2$	Cl	OH	$CH_3$	H	$NH_2$
$b_X$	0.516	-0.295	0.294	0.191	0.014	0.015
$(e_X)_m$	0.84	-0.45	-0.04	-0.13	0.00	-0.37
$(e_X)_p$	0.68	-0.04	0.57	0.07	0.00	-0.33

A comparison of the constants  $b_X$  for the *m*-substituted compounds with the values of  $b_X$  found for the *p*-substituted compounds<sup>1</sup> showed that for the given group of compounds  $\Delta b_X < 0.1$ , where  $\Delta b_X = (b_X)_p - (b_X)_m$ . We considered it advantageous to recalculate the  $b_X$  constants basing them on all data from both groups. Fig. 2 shows the results of this treatment; the constants  $b_X$ ,  $(e_X)_m$  and  $(e_X)_p$  are given in Table 2.

In our further work we intend to test the relationship between the given equation and linear free energy relationships (L.F.E.R.)<sup>2,3</sup> which have been already applied to biological problems, especially in papers by Zahradnik<sup>4,5</sup> and

Fig. 1.  $LD_{50}$  were determined on white mice (weighing  $20 \pm 2$  g) by the Thompson method. The substances were administered intravenously in a 20 per cent aqueous polyvinylpyrrolidone solution.

Fig. 2. See caption to Fig. 1.  $\circ$ , *Meta*-substituted derivatives;  $\bullet$ , *para*-substituted derivatives;  $\square$ , mono-substituted derivatives. Hydroquinol and resorcinol are omitted. If they are included the relationship between structure and biological activity becomes more complicated.

lately by Hansch<sup>6-8</sup>. This effort is supported by the surprising fact that the constants  $b_X$  are linearly dependent on the constants of  $f'_i$  obtained in the study of the thyroxine-like activity of 3,3',5,5'-substituted analogues of thyroxine<sup>9</sup>. The constants  $f'_i$  are also linearly dependent on the  $\sigma_m$ -constants.

At present the *o*-disubstituted derivatives of benzene are being studied in the same way, and simultaneously the number of substituents in the *p*-series is being extended to a more complete set of substances.

We thank Mr. Z. Roth for the statistical evaluation of our results.

### Relation of Magnesium Ions to Calcium and Phosphate Absorption

CHEMICALLY, magnesium and calcium are related since both elements are members of Group II of the Periodic Table. Physiologically, however, in plants<sup>1</sup> or in animals<sup>2</sup> their actions are often antagonistic. It has been shown that magnesium-deficient rats absorb more calcium from the gastrointestinal tract than do control rats<sup>3</sup> and the active transport of calcium ions across the intestinal wall of several species is depressed by magnesium ions<sup>4</sup>. These experiments indicate again a physiological antagonism between these ions and also suggest the possibility of a common absorptive pathway. However, the experimental conditions in the former study<sup>3</sup> are abnormal since magnesium is an integral part of normal diets and magnesium deficiency may have caused changes in the intestinal mucosa which allowed more calcium to be absorbed. *In vitro* type experiments<sup>5</sup> are, by their nature, unphysiological and extrapolations from such isolated systems to interpretations concerning overall calcium absorption *in vivo* may not be valid.

The literature is filled with conflicting reports concerning the relationship between magnesium intake and calcium balance. High magnesium intake has been reported to increase<sup>6-7</sup>, to decrease<sup>8,9</sup> and in some cases to have essentially no effect<sup>10-12</sup> on calcium balance. However, valid comparisons between these studies are impossible since different species were used, dietary regimens were very varied and in some cases the experiments were poorly controlled. Recently, it has been observed that increasing the magnesium intake tended to make calcium and phosphate balance more positive depending on the dietary Ca/P ratio<sup>13,14</sup>. These latter experiments, however, were designed for another purpose and lacked adequate control of dietary calcium and phosphorus. To determine whether magnesium, when administered to rats in amounts greater than required for adequate growth and maintenance, had any significant effect on calcium absorption, a series of experiments was carried out on rats fed diets of varied calcium and phosphorus composition. The animals supplemented with magnesium were pair fed with their controls. Excreta were collected during a 12-day period following a pre-treatment period of 5 days on the different diets and were analysed for calcium and phosphorus. Fig. 1 shows the effects of supplemental magnesium, administered as  $MgCl_2 \cdot 6H_2O$  in 10 per cent glucose drinking water, on faecal calcium. The control rats drank approximately the same volume of a 10 per cent glucose solution. With the exception of those animals fed diets containing only trace amounts of calcium, supplemental magnesium

Fig. 1. Faecal calcium (mg). Black, normal magnesium intake; white, supplemental magnesium

Fig. 2. Faecal phosphorus (mg). Black, normal magnesium intake; white, supplemental magnesium

decreased faecal calcium significantly. This was particularly evident at the higher levels of calcium intake. Thus, it is apparent that under normal dietary conditions, that is, in the presence of calcium in the diet, increasing the magnesium intake promoted calcium absorption rather than inhibited it. However, if the diet was essentially free of calcium (an abnormal condition), increasing the magnesium intake tended to decrease the absorption of calcium.

In Fig. 2 are shown the effects of supplemental magnesium on faecal phosphorus. When the calcium intake was low, magnesium increased faecal phosphorus, but if dietary calcium was 0.4 per cent or greater there was a tendency for decreased faecal phosphorus. Thus, magnesium will either increase or decrease phosphate absorption depending on dietary conditions.

### Effect of Carcinolipin on the Adenosine Triphosphatase Activity of Isolated Cellular Fractions

CARCINOLIPIN, the carcinogenic lipid isolated from biological materials<sup>1</sup>, was found to stimulate protein synthesis in cell-free systems<sup>2</sup>. However, it was not possible to decide if it affected this process directly or only indirectly, since protein synthesis is an energy-dependent reaction<sup>3</sup>.

Adenosine triphosphatase liberates energy by splitting ATP, which is an indispensable co-factor at all stages of protein synthesis<sup>2</sup>. Therefore, it was decided to elucidate the effect of carinolipin on this enzymatic activity in isolated subcellular fractions, in particular in those involved in protein synthesis.

Liver tissue from adult Wistar rats was homogenized in 0.25 M sucrose in a glass homogenizer with a plastic pestle to give a 5 per cent homogenate. This was centrifuged at 800g for 20 min to remove nuclei and cellular debris. Mitochondria were spun down from the resulting supernatant at 15,000g for 10 min, and microsomes were sedimented at 105,000g for 60 min. From the supernatant fraction, pH 5 enzymes were prepared in the usual way<sup>4</sup>.

Incubation mixtures contained 50  $\mu$ moles tris buffer, (pH 7.4), 2  $\mu$ moles  $\text{CaCl}_2$ , 2  $\mu$ moles ATP (sodium salt), carinolipin suspension (where indicated), and 0.1 ml. of finely homogenized cellular fractions in a total volume of 0.65 ml. They were incubated for 15 min at 37.5° C. Reaction was stopped by the addition of 0.1 ml. 50 per cent trichloroacetic acid, precipitated proteins were centrifuged off and inorganic phosphate was determined in the supernatant by the Fiske-Subbarow method<sup>5</sup>. The protein content of each subcellular fraction was determined as described by Lowry *et al.*<sup>6</sup>, and the results were expressed as  $\mu$ moles inorganic phosphate liberated per hour per mg protein nitrogen.

The mitochondrial fraction showed the highest adenosine triphosphatase activity of all cellular preparations tested. The activity of microsomes was also relatively high, while low enzymatic activities were found in the cell sap and pH 5 enzymes. Average values from five similar experiments with different batches of liver tissue are given in Table 1.

Table 1. ADENOSINE TRIPHOSPHATASE ACTIVITY OF VARIOUS CELLULAR FRACTIONS

Fraction	Phosphate liberated
Whole liver homogenate	0.050
Mitochondria	3.000
Microsomes	0.235
Cell sap	0.054
pH 5 enzymes	0.049

Addition of carinolipin in various doses had no effect on adenosine triphosphatase activity of cellular supernatant and pH 5 enzymes. A stimulation, however, was seen when mitochondrial fraction and microsomes were used. The most effective dose of carinolipin was 5  $\mu$ g, while higher as well as lower doses of this substance were less effective. A summary of these results (mean values of four experiments) is given in Fig. 1.

It appears from these results that a stimulation of energy-yielding reactions by an increased splitting of ATP cannot explain the stimulating effect of carinolipin on protein synthesis. No stimulation of adenosine triphosphatase was found with pH 5 enzymes, which are the only fraction necessary for the first step of protein syn-

Fig. 1. Effect of various doses of carinolipin on the adenosine triphosphatase activity of rat liver homogenate (full line), mitochondria (dashed line), and microsomes (dotted line).

thesis<sup>4</sup>. It is this first step which is highly stimulated in the presence of carinolipin<sup>4</sup>. Moreover, although the adenosine triphosphatase activity of microsomes is stimulated by this substance, the degree of this enhancement is rather low when compared with the stimulating activity of carinolipin on protein synthesis in a complete cell-free system<sup>3</sup>. From our results it would thus scarcely seem probable that carinolipin affects protein synthesis to any significant extent by increased liberation of energy from adenosine triphosphate.

### Preparation of an Active Mitochondrial Fraction from the Fruit of *Mangifera Indica*

In connexion with biochemical studies of the effect of growth regulators on the ripening pattern of fruit, it was necessary to isolate a mitochondrial fraction which had respiratory activity with Krebs cycle intermediates as substrates. Considerable difficulty was encountered during the initial attempts at isolation because of the highly acidic nature of the fruit pulp. This problem of low pH has been overcome by using dipotassium phosphate during the isolation procedure for mitochondria from apple<sup>1</sup>, or using an alkaline buffer of pH 9.2<sup>2</sup>. This note reports the isolation of a mitochondrial fraction with tricarboxylic acid cycle activity from the mango fruit. All the operations were carried out at 0°–4° C. Preliminary fruits stored at 21° C were used.

Mitochondria were isolated essentially by the method of Tager<sup>1</sup>, with a few modifications. The homogenizing medium consisted of 0.5 M sucrose–0.1 M phosphate–0.01 M EDTA solution. To 100 ml. of this solution, 77 mg cysteine hydrochloride, 100 mg bovine plasma albumin and 420 mg sodium fluoride were added just before use and the pH was adjusted to 7.4. 100 g mango pulp was homogenized in a blender with 100 ml. of the homogenizing medium. To neutralize the acids released during homogenization, 70–90 ml. of 0.5 M sucrose–1.0 M dipotassium hydrogen phosphate solution (the actual volume being fixed by trial with another aliquot from the same sample) was added at intervals during the one-minute homogenization period. Under these conditions, the pH of the homogenate was always maintained at about 7.4. The mitochondrial pellet sedimenting at 7,000 g was washed twice with 0.5 M sucrose–0.1 M phosphate–0.01 M EDTA buffer solution and suspended in 0.33 M sucrose.

Preliminary experiments indicated considerable increase in succinoxidase activity in the presence of externally added cytochrome c. Hence it was routinely added in all the experiments. In a typical experiment in the present series, oxygen consumption rose from 22 to 43  $\mu$ l./h/mg protein, after addition of cytochrome c. Weiskich and Bonner<sup>3</sup> have recently reported the isolation of mitochondria from sweet potato which did not require cytochrome c addition.

Oxidation of the various substrates was followed manometrically and the results are given in Table 1. Mitochondria prepared in the present experiments had no endogenous oxygen uptake. Succinate oxidation values compared favourably with those reported for another acidic fruit (apple) by Tager ( $\text{QO}_2$ (N), 108–276), but are lower than those reported by Hulme *et al.*<sup>4</sup> when polyvinylpyrrolidone was used in the isolation medium.

Table 1. CITRATE AND SUCCINOXIDASE ACTIVITIES OF MITOCHONDRIAL FRACTIONS FROM LOCAL VARIETIES OF *Mangifera indica* (PEROLIMACTHERIO)

Variety	O <sub>2</sub> uptake/ $\mu$ l./h/mg protein	
	Succinate	Citrate
'Kalapahar'	80	9
'Totapuri'	52	19
'Chittor Yamini'	62	11
'Titar Pasand'	85	8
'Lal Pasand'	30	5
'Pairi'	40	9

(The values are averages of four independent observations)

Each Warburg flask contained phosphate 80  $\mu$ moles, sucrose 800  $\mu$ moles, substrate 20  $\mu$ moles, cytochrome c 4 mg; MgSO<sub>4</sub>·7H<sub>2</sub>O, 10  $\mu$ moles, final volume 3.2 ml., pH 7.4, temp 35° air phase.

Table 2. DEHYDROGENASE ACTIVITIES OF MITOCHONDRIAL FRACTION FROM PULP OF 'PAIRI' VARIETY (PEROLIMACTHERIO)

Dehydrogenase	Isocitrate	Oxaloacetate + NADH	Diaphorase	NADH Cyt C reductase
Units*	0.025	0.676	0.932	1.87

(The values are averages of four independent observations)

\* Optical density change/min/mg protein.

Malate and pyruvate oxidations were also studied for the 'Pairi' variety in the Warburg apparatus and the respiration rates obtained were between 5 and 10  $\mu$ l. O<sub>2</sub>/h/mg protein. The dehydrogenase activities are reported in Table 2. Isocitrate and oxaloacetate + NADH reactions were followed in a Beckman 'DU' spectrophotometer<sup>2</sup>. Diaphorase and NADH-cytochrome c reductase were assayed by the method of Mahler *et al.*<sup>3</sup>

The results presented here have shown the possibility of isolating an actively respiring mitochondrial fraction from the mango fruit. Further, these mitochondria showed respiratory control when tested with the vibrating platinum electrode technique<sup>4</sup> with succinate as substrate in the presence of adenosine diphosphate. Further work on respiratory control and the biochemical properties of mitochondria during various stages of ripening of the fruit is in progress.

I thank Mr. H. Subrahmanyam for providing the fruits.

### Anthocyanins in Ferns

THE water-soluble red pigments present in young fern fronds do not seem to have been investigated since Price, Sturgeess, Robinson and Robinson<sup>1</sup> in 1938 reported that unusual flavylum salts, resembling 6-hydroxypelargonidin or 6-hydroxycyanidin in their colour properties, occurred in eight ferns. Recent phytochemical interest in the phenolic constituents of lower plants<sup>2</sup> and the discoveries of luteolinidin (I, R = OH) in the moss *Bryum*<sup>3</sup> and of an unidentified anthocyanidin in a fungus<sup>4</sup> suggested that the fern pigments would bear re-investigation.

Two ferns, *Adiantum verticillatum* and *Pteris quadrifaria*, closely allied to those examined by Price *et al.*<sup>1</sup>, were investigated. Extracts of juvenile fronds were hydrolysed with acid and the aglycones produced compared by chromatographic and spectral analysis with authentic anthocyanidins (Table 1). The two aglycones present in *A. verticillatum* were identified as apigeninidin (I, R = H) and luteolinidin (I, R = OH) and that of *Pteris* as luteolinidin. Both these pigments were readily

Table 1. CHROMATOGRAPHIC AND SPECTRAL PROPERTIES OF FERN ANTHOCYANIDINS

\* Solvent A is the Forestal mixture, B is H<sub>2</sub>O-HCl-H<sub>2</sub>O (9:2:3), C is butanol-acetic acid-water (4:1:5) and D is ethyl acetate-H<sub>2</sub>O-2N HCl (85:9:6). Separations using A, B and C were carried out on Whatman No. 1 paper, those with D on silica gel.

† Also gives an AKI, shift of 52 m $\mu$ .

differentiated by R<sub>F</sub> value from pigments having similar colour properties, that is, 6-hydroxypelargonidin (II, R = H, R' = OH) and 6-hydroxycyanidin (II, R = R' = OH), both of which were available for comparison (Table 1). That these two anthocyanidins occur in some unusual combined form and not as simple sugar derivatives follows from the fact that (a) the natural pigments were more resistant than usual to acid hydrolysis, and (b) the pigments in the frond extracts differed in R<sub>F</sub> value from the known apigeninidin and luteolinidin 5-glucosides<sup>5</sup>. The two pigments in *Pteris*, for example, had R<sub>F</sub> values that were higher in both alcoholic and aqueous solvents (0.71 and 0.66 in butanol-2 N HCl (1:1), 0.38 and 0.28 in 1 per cent aq. HCl) than either luteolinidin or its 5-glucoside (0.60 and 0.27 in butanol-HCl, 0.03 and 0.12 in 1 per cent HCl, respectively).

The occurrence in both ferns and mosses of these rare anthocyanidins, which are biogenetically related to the flavones rather than to the flavonols, is of considerable phytochemical interest. It suggests that these plants lack the ability to add a 3-hydroxyl group to a specific C<sub>15</sub>-intermediate to yield the usual type of anthocyanidin such as cyanidin (II, R = OH, R' = H) found in higher plants. The suggestion that apigeninidin and luteolinidin production is a 'primitive' character is not necessarily contradicted by the fact that these rare pigments are also found in the petals of one of the most 'advanced' families of higher plants, the Gesneriaceae<sup>6</sup>. They are presumably produced in this family in response to selection for orange-red flower colour. It should, however, be pointed out that a few ferns do appear to have normal anthocyanins, since cyanidin and pelargonidin glycosides have been reported in *Davallia divaricata*<sup>1</sup> and in *Dryopteris erythrosora*<sup>7</sup>. Furthermore, many ferns contain the flavonols kaempferol and quercetin<sup>8</sup> as well as leucocyanidin<sup>9</sup>. Investigations of the distribution in the Pteridophyta of anthocyanidins, with and without 3-hydroxyl groups, are therefore in progress.

### Phenolic Compounds in Roots and Leaves of Four Citrus Cultivars

As part of an investigation of the biochemical changes associated with the decline of citrus trees caused by the burrowing nematode, *Radopholus similis* (Cobb) Thorne, a study was undertaken on the isolation of growth promoters and inhibitors in both the roots and young branch terminals. Since a number of phenolics have been identified as co-factors for indolyl-3-acetic acid (IAA) oxidase<sup>1</sup>, a better understanding of the type of growth associated with citrus decline would involve information concerning possible changes in the phenolic constituents. Another reason for consideration is the participation, if any, of phenolics in host resistance either prior to or after pathogenesis. This portion of the investigation is concerned with the extraction, chromatography and identification of the free and acid hydrolysable (bound) phenolics in the leaves and roots of 4 citrus cultivars.

The citrus cultivars used in this investigation comprise two susceptible and two tolerant to *R. similis*. The susceptible cultivars were *Citrus paradisi* Macf. var. 'Duncan' and *C. limon* Osbeck; the tolerant cultivars were *C. sinensis* Osbeck var. 'Ridge Pineapple', and 'Milam', a citrus hybrid of unknown parentage<sup>2</sup>.

Fresh feeder roots and leaves from healthy, two-year-old greenhouse grown seedlings were used for extraction. 100 g tissue was triturated in a Waring blender with hot 95 per cent ethanol, boiled on a water bath for 1 h, and filtered hot through a sintered glass funnel. The solvent was removed under reduced pressure in a rotary film evaporator and the residue was triturated in a small quantity of hot water for subsequent free<sup>3</sup> and acid-hydrolysable<sup>4</sup> (bound) phenolic extraction.

Two-dimensional ascending chromatography was employed using Whatman No. 1 paper 22 cm<sup>2</sup>. Chromatograms were spotted with the equivalent of 250–500 mg plant material. The first direction solvent system was benzene-acetic acid-water (125 : 72 : 3) v/v/v, equilibrated at least 5 h at 17° C prior to use. After drying overnight at 26° C, the second direction was developed in sodium

formate-formic acid-water (10 : 1 : 200) w/v/v, at 26° C. Good resolution and excellent *R<sub>F</sub>* reproducibility were obtained with these solvents at these temperatures. Chromatograms were viewed with and without ammonium hydroxide vapours under ultra-violet light at 3660 Å and at 2537 Å. Further identification was obtained by 2 diazo sprays, *p*-nitraniline and sulphanilic acid. The identity of the phenolic compound was confirmed by co-chromatography with authentic substances.

Fifty-eight phenolics were found in the roots and leaves of the 4 citrus cultivars; 36 and 37 of these were found in the susceptible and 45 and 46 in the resistant cultivars. Twenty-six phenolics were identified. Many of the unidentified phenolics appeared on the chromatograms as small fluorescent spots and were considered as trace amounts (0.5 µg or less). Seven of the unidentified phenolics were present in sufficient amounts (about 10 µg or more) to warrant additional study and identification. The relative amounts of each of the phenolics identified in the free and acid hydrolysed fractions are shown in Table 1. In general, there were 2–3 times as many bound phenolics as free phenolics. Approximately the same number and kinds of bound phenolics were found in the leaves and roots of the 4 cultivars, but the quantities of the bound phenolics were greater in the roots than in the leaves. The free phenolics in the roots were also present in greater numbers and in larger amounts than in the leaves.

Ferulic acid, sinapic acid, *p*-coumaric acid and *p*-hydroxybenzoic acid were present in large amounts in the acid-hydrolysed fraction of both roots and leaves. Umbelliferone and scopoletin were present in large amounts in roots and leaves of *C. limon* and *C. paradisi* and in the roots of *C. sinensis* and 'Milam'. These 6 phenolics plus several closely related phenolics have been shown to influence certain physiological functions in plants, particularly as related to growth<sup>5</sup>, dormancy and photo-induction<sup>6</sup>, and IAA oxidase activity<sup>1</sup>.

Phloretin and esculetin were found only in the acid-hydrolysed fraction of *C. limon* leaves. This is the first reported occurrence of phloretin in citrus, although it was

previously reported in *Micromelum tophocarpum* Turcz. which is in the citrus family, Rutaceae<sup>7</sup>. Esculetin appears to be a natural constituent and not likely to have been pre-formed from *o*is-caffeic acid during chromatography since even small amounts of the latter could not be detected in either the free or bound form<sup>8</sup>. This is also the first report of the occurrence of the hydroxybenzoic acids in citrus, and with the exception of *p*-coumaric acid and sinapic acid, none of the cinnamic acids listed has been previously reported (Table 1).

The identification of galangin is tentative since an unknown phenolic with an *R<sub>F</sub>* close to galangin interfered with separation and identification.

## PHYSIOLOGY

### An Effect of Sugars on Fluid Entry into Erythrocytes

WHEN human erythrocytes are suspended in a salt solution containing glucose, the sugar enters the cells and establishes an osmotic gradient across the cell membrane. Consequently water follows the glucose into the erythrocytes, causing the cells to swell and ultimately to haemolyse. Some investigators<sup>1-4</sup> have used the rate of swelling or haemolysis as a measure of rate of sugar entry into the cells. An example of the results obtained by this method is shown in Fig. 1. Since the total osmolarity of the suspending medium was not changed on addition of the sugar solutions in this experiment, the observed haemolysis can be ascribed to sugar entry into the cells. However, the kinetic interpretation of such data seems uncertain, for we observed that sugars also tend simultaneously to depress the rate of fluid entry into the erythrocytes.

Fig. 1. Haemolysis of human erythrocytes in the presence of different sugars. Two ml. of a 0.1 per cent suspension of erythrocytes was equilibrated in 0.1 M NaCl at 37° C and then mixed at zero time with 1 ml. of 0.2 M sugar solution (1, L-arabinose; 2, D-galactose; 3, D-glucose; 4, L-sorbose). The rate of increase in per cent light transmittance at 550 mμ, measured on a Beckman DK-2 recording spectrophotometer, indicated the rate of haemolysis.

Fig. 2. Haemolysis in hypotonic media. At zero time, 2 ml. of 0.05 M NaCl or of 0.1 M glucose or of mixtures of these two solutions were added to 1 ml. of a 0.1 per cent suspension of human erythrocytes in 0.15 M NaCl. In all cases, the total osmolarity of the added solutions was the same. The glucose concentrations in the added solutions were: 1, 0 M; 2, 0.05 M; 3, 0.025 M; 4, 0.0125 M; 5, 0.00625 M. Sample (6) contained 2 ml. of 0.1 M sucrose. Other details are the same as in Fig. 1.

This depressor effect could be demonstrated clearly when the osmotic gradient was established by lowering the osmolarity of the extracellular fluid (Fig. 2). An appreciable haemolysis occurred rapidly, as might be expected, when 1 vol. of an erythrocyte suspension in 0.15 M sodium chloride was mixed with 2 vol. of 0.05 M sodium chloride. An identical rate of haemolysis was obtained with lithium chloride, potassium chloride and caesium chloride. However, the addition of 2 vol. of sucrose solution of the same osmolarity did not produce haemolysis, while addition of glucose solutions delayed the onset of haemolysis quite markedly as compared with the results observed in hypotonic saline (Fig. 2). This delay in haemolysis increased as the concentration of glucose was increased. Haemolysis did occur eventually in the glucose solutions, presumably because the glucose itself entered the cells in the same manner as illustrated by Fig. 1. Sugars which penetrated the cells most slowly produced the greatest delay in fluid entry under these conditions; thus the time to haemolysis in hypotonic media increased in the series arabinose, galactose, glucose, sorbose, sucrose. Further, the depression of fluid entry by glucose was much more marked with rat erythrocytes, which are reported to be less permeable to glucose<sup>5</sup>, than with human erythrocytes.

Possibly the sugar molecules are adsorbed on to the erythrocyte membrane and thus block the entry of water through water-filled pores in the membrane. This hypothesis is supported by the results obtained with phloretin. Phloretin, which has often been used as a specific inhibitor of entry of glucose into erythrocytes, is known to be strongly adsorbed on to the erythrocyte membrane<sup>6</sup>. We observed that 0.03 mM phloretin not only delayed haemolysis in the presence of glucose, as expected, but also delayed haemolysis in hypotonic sodium chloride solution. Apparently phloretin, too, interfered with the entry of water into the erythrocytes. (Exposure to X-radiation in doses above 1 krad, on the other hand, seemed to facilitate glucose and fluid entry into human erythrocytes, but the mechanism of this effect requires further study.)

The foregoing results suggest that extreme caution should be exercised in the interpretation of results where cell swelling or time of haemolysis is used as a measure of the rate of sugar entry into erythrocytes. Several authors have, for example, reported that the permeability constant for glucose decreases with increasing glucose concentration<sup>1-4</sup>. These results could simply be due to a

depression of the rate of fluid entry at high concentrations of sugar.

### Cardiovascular and Metabolic Effects of Adenosine 3',5'-Monophosphate *in vivo*

CATECHOLAMINES activate the enzyme, adenylyl cyclase, which forms cyclic adenosine 3',5'-monophosphate (3',5'-AMP) in a variety of animal tissues<sup>1</sup>. This reaction system has been thought to control several metabolic processes, including glycogenolysis, steroidogenesis, ketogenesis, lipolysis and antidiuresis<sup>2-4</sup>. The positive inotropic and chronotropic effects of catecholamines on the heart are generally attributed to catechol interaction with the beta adrenergic receptor site. Rall and Sutherland<sup>5</sup> and Mayer *et al.*<sup>6</sup> have proposed that 3',5'-AMP might directly affect cardiac beta receptors by mediating hormone-induced changes in contractile force without necessarily involving glycogenolysis. During the course of investigations in the isolated perfused rat liver, 3',5'-AMP was observed to induce delayed vasomotor changes unrelated to its glycogenolytic action<sup>10</sup>. This suggested that 3',5'-AMP might have a direct vascular effect on smooth muscle. Although 3',5'-AMP produces hyperglycaemia in intact animals<sup>1,10-12</sup>, correlation of its metabolic action with possible regulation of cardiac activity has not been previously investigated.

Prior to the use of 3',5'-AMP in humans, toxicological investigations were carried out in 59 male Sprague-Dawley rats (250 g), 66 adrenalectomized male rats of the same strain, 12 guinea-pigs, 59 New Zealand rabbits and 27 adult mongrel dogs following single intravenous or intracardiac doses of 3',5'-AMP (4-100 mg/kg). No anaphylactic or adverse clinical reactions were observed. After the safety of the cyclic nucleotide was established in animals, metabolic and cardiovascular responses were also investigated in 14 male and six female human volunteers.

Animals and humans either received food as desired or were kept fasting for 12-36 h. Blood glucose was determined after deproteinization by the glucose oxidation procedure of Cawley *et al.*<sup>14</sup>. Plasma non-esterified fatty acids (FFA) were measured by the method of Dole<sup>15</sup>. Plasma cortisol was estimated as Porter-Silber chromogens by the method of Peterson *et al.*<sup>16</sup>. Plasma osmolality was determined by freezing-point depression with the use of a Fiske osmometer. All blood samples in the rats and rabbits were determined at either 10 or 20 min after injection of 3',5'-AMP. Detailed haemodynamic measurements were performed in dogs and humans. Dogs were prepared with catheters chronically implanted in the right atrium and aortic arch. All measurements in the dogs were made with the animal lying unrestrained, and determinations of cardiac output, heart rate, and mean blood pressure were recorded. 3',5'-AMP (4-8 mg/kg) was administered as a single intracardiac dose into the right ventricle, during cardiac catheterization, to eight human volunteers, by rapid intravenous injection to seven subjects, and by constant intravenous infusion to five others, at the rate of 0.5 mg/kg/min for a period of 1-2 h. The cyclic nucleotide was prepared as a fresh solution, diluted in saline, adjusted to a pH of 7.40, and,

in the case of human experiments, filtered through a monomolecular 'Millipore' filter prior to use. All the animals and humans who received food *ad lib.* demonstrated hyperglycaemia, but there was considerable variation and marked species differences in the FFA response. Table 1 summarizes experiments in the non-fasted state in which glucose and FFA were simultaneously determined.

Table 1. EFFECT OF 3',5'-AMP ON BLOOD GLUCOSE AND FFA

Species†	No. of expts.	Blood glucose* (mg/100 ml.)			FFA* (m equiv./l.)		
		Initial	Response‡	P <	Initial	Response‡	P <
Rat	14	107 ± 14	172 ± 46	0.001	532 ± 183	830 ± 614	ns
Adrenalectomized rat	15	118 ± 13	167 ± 53	0.005	418 ± 137	641 ± 276	0.025
Rabbit	16	92 ± 24	165 ± 19	0.035	883 ± 152	805 ± 584	ns
Dog	24	85 ± 13	118 ± 15	0.001	880 ± 460	509 ± 286	0.005
Man	9	98 ± 12	182 ± 14	0.025	596 ± 304	757 ± 468	ns

\* Results are the means ± standard deviation.

† Rats were anaesthetized with ether anaesthesia while rabbits, dogs, and humans were unanaesthetized.

‡ Response observations represent maximal values after single intravenous or intracardiac administration of 3',5'-AMP (4-12 mg/kg).

In 27 fed and fasted dogs, following single intracardiac doses of 3',5'-AMP (4-8 mg/kg), heart rate increased within seconds. Maximal mean increase in cardiac rate (+57 per cent) and cardiac output (+43 per cent) occurred at 2 and 5 min, respectively. These effects were statistically significant ( $P < 0.001$ ). Cardioacceleration remained significant for 15 min ( $P < 0.025$ ). There was a transient decrease in mean blood pressure, which was statistically significant only during the first 3 min after 3',5'-AMP administration ( $P < 0.001$ ). Calculated total peripheral resistance was significantly diminished at 5 min ( $P < 0.001$ ) and at 15 min ( $P < 0.010$ ). There were no significant changes in stroke volume or mean pulse pressure. Mean glucose increased to a maximum at 7 min (+45 per cent) and then decreased at 10 min (+39 per cent), and 15 min (+24 per cent). As glucose increased, FFA progressively decreased to a maximum at 15 min (-46 per cent). From the time relationships of the maximal changes in glucose and FFA in dogs, it appears that the decrease in FFA is causally related to the 3',5'-AMP-induced hyperglycaemia. No significant cardiac or metabolic changes followed administration of saline or 2',3'-AMP, 5'-AMP, and ATP, which were given in doses equimolar with 3',5'-AMP. Prior treatment with the beta adrenergic blocking agent, propranolol, at dosages of 0.1-0.5 mg/kg, produced a moderate decrease in heart rate, but no biochemical alterations. Pre-treatment with propranolol failed to prevent the cardiac and biochemical responses to 3',5'-AMP, suggesting that 3',5'-AMP does not act directly on beta receptors in order to elicit its action.

Following rapid intravenous or intracardiac administration of 3',5'-AMP to 15 human subjects, cardiac rate increased within seconds. The maximal increase in heart rate averaged 40 per cent above control values ( $P < 0.005$ ) at 5 min. Tachycardia persisted for 15 min. Cardiac output, in the eight subjects studied during cardiac catheterization, increased to a mean of 44 per cent ( $P < 0.025$ ), and total peripheral resistance decreased to a mean of 34 per cent ( $P < 0.005$ ) 5 min after 3',5'-AMP injection. There were no significant changes in stroke volume, systolic or diastolic blood pressure. In those subjects who received a constant infusion of 3',5'-AMP, blood pressure promptly increased an average of 22 per cent above initial values and remained elevated throughout the period of infusion, associated with cardioacceleration (+20 per cent). Hyperglycaemia was consistently observed in all 20 subjects with a maximal mean increase 10 min after 3',5'-AMP administration. FFA response was variable. Plasma cortisol determinations, obtained

on the day preceding the infusion experiments, decreased in all five subjects. On the following day, when 3',5'-AMP was given as a constant infusion, plasma cortisol rose from an initial mean value of  $11.7 \pm 3.5$   $\mu\text{g}/100$  ml. to  $24.6 \pm 9.0$   $\mu\text{g}/100$  ml. ( $P < 0.025$ ) at the end of the infusion. In 15 acute injection experiments plasma cortisol significantly increased in six ( $P < 0.025$ ), remained unchanged in seven, and decreased in two. There were no significant changes in plasma osmolarity in any subject. No electrocardiographic abnormalities or arrhythmias followed administration of the nucleotide in humans or dogs. Several clinical side-reactions to 3',5'-AMP were observed in all five subjects receiving a constant infusion and in four others who received a single dose of nucleotide. These included abdominal pain in eight, headache in seven, nausea in four, fatigue in four, sweating in three, testicular pain in three, vomiting in two, tenesmus in two, and conjunctival suffusion in two.

The results of this investigation indicate that 3',5'-AMP penetrates intact cell membranes in significant concentration to regulate intracellular metabolic events, as reflected by glycogenolysis, steroidogenesis and possibly lipid homeostasis. Experiments in the isolated perfused rat heart have shown that epinephrine rapidly increases cardiac 3',5'-AMP and phosphorylase content associated with a positive inotropic effect<sup>17</sup>. The actions of 3',5'-AMP to increase the output and rate of the heart *in vivo* lend support to the hypothesis obtained from *in vitro* data that 3',5'-AMP may represent the biochemical basis for the myocardial response to catecholamines. These results give no conclusive indication of a positive effect on myocardial contractility (inotropic action) since direct measurements of myocardial contractile force were not performed. From the time sequences of the peak responses of heart rate and blood glucose to the cyclic nucleotide, it would appear that the prompt cardiovascular actions were independent of the observed delayed hyperglycaemia.

We thank Dr. Dalton Jenkins, University of Colorado School of Medicine, for the plasma cortisol determinations and Drs. Robert B. Franklin and Leon M. Dixon, Cardiology Service, Fitzsimons General Hospital, for the cardiac catheterization investigations on humans. 3',5'-AMP was provided by Schwarz BioResearch, Inc., Orangeburg, New York.

## Hormonal Regulation of Cardiac Muscle Citrate

A CONSIDERABLE amount of evidence indicates that phosphofructokinase (PFK) is of importance in regulating the rate of glycolysis in a number of tissues<sup>1-3</sup>. In turn, glucose-6-phosphate, which accumulates when PFK is inhibited, has an inhibitory effect on the phosphorylation of glucose<sup>4</sup>. Thus, alterations of PFK activity may have a significant influence on carbohydrate utilization. *In vitro*, the activity of PFK may be altered by a multiplicity of factors<sup>5,6</sup>, some inhibitory and others stimulatory. One of the inhibitory substances is citrate<sup>8,11</sup>, and some evidence that citrate may be an inhibitor *in vivo* derives from the observation that citrate is elevated and PFK activity is depressed in hearts of diabetic rats and in normal hearts perfused with fatty acids<sup>8,11</sup>. Likewise, in hearts exposed to fluoroacetate, in which citrate rises to high levels, there is an inhibition of PFK<sup>12</sup>.

Hypophysectomy has long been known to alleviate certain of the metabolic disturbances of diabetes, and in perfused hearts from diabetic animals the slow rate of glucose phosphorylation is greatly improved when the donor animals have also been hypophysectomized<sup>13</sup>. If citrate is in part responsible for inhibited PFK activity and depressed glucose phosphorylation in cardiac muscle of diabetic animals, the citrate-level should return toward normal after the pituitary is removed. Likewise, adrenal cortical hormones are known to aggravate diabetes; thus it might be expected that citrate would be elevated in animals treated with these hormones. The present data show that the level of heart muscle citrate follows these expectations.

Male rats, fed *ad libitum*, were used as the source of tissue in all the experiments. The animals were anaesthetized with sodium pentobarbital and the hearts were exposed and frozen *in situ* between blocks of aluminium previously cooled in liquid nitrogen. In some cases the hearts were quickly excised and then frozen by the same method. No difference was found between the two methods and the results have been pooled.

Normal and hypophysectomized rats were made diabetic by injection of alloxan at a dosage of 60 mg/kg administered intravenously. The serum glucose was in excess of 500 mg/100 ml. serum in all animals given alloxan. The hearts were removed 48 h after the alloxan injection, powdered in a stainless steel mortar at liquid nitrogen temperature, extracted in 10 per cent trichloroacetic acid and assayed for citrate by the pentobromacetone method<sup>14</sup>.

The results are presented in Table I, and, as reported previously<sup>8</sup>, citrate was elevated in the heart muscle of diabetic rats. Hypophysectomy of non-diabetic rats caused some decrease in the citrate concentration, and in diabetic animals hypophysectomy resulted in citrate-levels intermediate between those found in hearts of normal and diabetic rats. When growth hormone and hydrocortisone were injected into hypophysectomized-diabetic rats the citrate-level was significantly elevated beyond that found in hearts from diabetic animals. Likewise, when normal animals were injected with growth hormone and hydrocortisone there was a small increase in heart muscle citrate. Presumably, in the intact animal any large increment in citrate would be prevented by insulin secretion. Insulin previously has been shown to reverse the elevated citrate values in heart muscle of diabetic rats<sup>8</sup>, and the effect is also shown in hypophysectomized animals, which are more sensitive to insulin, in the present data.

The results suggest that diabetes, growth hormone and adrenal cortical hormones may exert a part of their inhibitory effect on glucose phosphorylation via a depression in PFK activity brought about by an elevation of tissue citrate. The hormonal effects on citrate may, in turn, be mediated through alterations in the level of plasma free fatty acids (FFA). The various endocrine conditions

Table 1. EFFECT OF SEVERAL HYPOPHYSECTOMY CONDITIONS ON THE LEVEL OF CARDIAC MUSCLE CITRATE IN MALE RATS

Condition	Cardiac muscle citrate ( $\mu$ moles/g dry wt.)
Untreated	$2.2 \pm 0.17^{\dagger}$ (16) <sup>¶</sup>
Alloxan*	$5.1 \pm 0.34$ (16)
Hypophysectomized	$1.7 \pm 0.14$ (10)
Hypophysectomized plus alloxan	$3.2 \pm 0.2$ (16)
Hypophysectomized plus alloxan plus insulin†	$0.8 \pm 0.05$ (4)

¶ Number of animals in each group.

reported here to cause a rise in citrate are accompanied by an increase in plasma FFA<sup>12-17</sup>, and perfusion of normal hearts with fatty acids elevates the citrate level<sup>8,11</sup>. The mechanism for the rise in citrate induced by fatty acids is not yet clear. However, preliminary results<sup>18</sup>, and other data obtained by us, show that the rise in citrate in hearts perfused with fatty acids, or in hearts of diabetic rats, is not limited to this one intermediate of the tricarboxylic acid cycle. Rather, there is an overall increase in the level of the cycle intermediates. Whether there is also an alteration in the rate at which the cycle operates has not been determined.

## HAEMATOLOGY

## Iodine-125-labelled L Chains of Human Blood Group Antibodies

Cohen and Porter<sup>1</sup> have demonstrated that the light (L) chains of human IgG globulins can be separated into ten subfractions by starch-gel electrophoresis. They also showed that the L chains of guinea-pig anti-ovalbumin and anti-(bovine serum albumin) separated into ten subfractions, but the intensity of the staining of the bands differed from each other and from those of L chains obtained from IgG globulins. The work presented here is concerned with the distribution of <sup>125</sup>I-labelled L chains of human antibody among the ten subfractions.

L chains were prepared from three different sources by the method of Fleischman, Pain and Porter<sup>2</sup>. (1) <sup>125</sup>I-labelled L chains were isolated from six different examples of purified <sup>125</sup>I-labelled anti-D and from two different anti-c antibodies; these antibodies were obtained from women who had given birth to a child with haemolytic disease. Purified <sup>125</sup>I-labelled antibodies were obtained by a method previously described<sup>3</sup>; at least 90 per cent of the iodine-125 in the final preparation represented active antibody. Approximately 20  $\mu$ g of <sup>125</sup>I-labelled antibody was added to 50 mg of unlabelled pooled IgG globulin before isolation of the L chains. (2) <sup>125</sup>I-labelled L chains were isolated from IgG globulin obtained from each of the eight antisera after absorption of the antibody; 20  $\mu$ g of <sup>125</sup>I-labelled IgG globulin were added to 50 mg of unlabelled pooled IgG globulin before isolation of the L chains. (3) L chains were prepared from 50 mg of pooled IgG globulin, all of which had been labelled with iodine-125 prior to isolation of the L chains. The ratio of the optical densities at 280 m $\mu$  of the solutions of separated H and L chains was approximately 75/25 and the ratio of the iodine-125 content in each was approximately 85/15. The iodine/protein ratio was approximately 2/1 (atoms/molecule) except in the case of the pooled IgG globulin where it was 6/1. All preparations of L chains were subjected to starch-gel electrophoresis<sup>4</sup> at pH 9.0. Following electrophoresis, the surface of the gel was stained and the distribution of the stained bands was recorded. The distribution of iodine-125 was then determined by cutting the gel into 2-mm sections and estimating the radioactive content of each section.

A comparison was made between the electrophoretic mobility of <sup>125</sup>I-labelled L chains (preparation 3) and unlabelled L chains obtained from pooled IgG globulin. On staining the starch gel, the <sup>125</sup>I-labelled L chains showed ten 'major' bands which ran in the same position as the L chains obtained from unlabelled IgG globulin. However, between the 'major' bands there were less-intensely staining 'minor' bands which were not present in the unlabelled L chains. These 'minor' bands had moved further towards the positive pole than their corresponding 'major' components. The iodine-125 was found to be distributed in ten 'peaks' of activity, each peak corresponding to the 'minor' bands seen on staining (Fig. 1). These results suggest that not all the L chains are labelled with iodine and those chains that are labelled are more electronegative than the unlabelled chains. Failure to label all the chains may be due to inadequate mixing of iodine-125 and protein during the labelling process, or may be due to heterogeneity of L chains, not all of which may have tyrosine available for labelling. The increased electronegativity of the labelled L chains may be related to the presence of di-iodotyrosine in the peptide chains. The pK (OH) value of L-tyrosine is 10.07, whereas the corresponding value of di-iodo-L-tyrosine is 6.48 (ref. 4).

The distribution of the <sup>125</sup>I-labelled L chains (preparation type 2) obtained from the IgG globulin isolated from each of the eight antisera was closely similar to the

Fig. 1. Starch-gel electrophoresis of  $^{125}\text{I}$ -labelled and unlabelled  $L$  chains. The upper part shows the position of the stained bands (amido-black) and the lower graph shows the distribution of iodine-125. The shaded blocks represent the 'major' bands and the unshaded blocks the  $^{125}\text{I}$ -labelled 'minor' bands. The  $^{125}\text{I}$ -labelled  $L$  chains are more electro-negative than the unlabelled chains.

Fig. 2. Starch-gel electrophoresis of  $^{125}\text{I}$ -labelled  $L$  chains obtained from six anti-D (labelled D) and two anti-c (labelled c) antibodies. The histograms give the relative distribution of iodine-125 found in each of the ten subfractions. The numbering of the bands is that used by Cohen and Porter (ref. 1).

distribution of the  $L$  chains from pooled  $^{125}\text{I}$ -labelled  $\gamma$ -globulin (preparation 3).

The distribution of  $^{125}\text{I}$ -labelled chains from the purified antibodies (preparation type 1) differed from each other and from those obtained from IgG globulin from the respective antisera (Fig. 2). The minimum number of  $^{125}\text{I}$ -peaks seen in each example was four and the maximum nine. Three preparations of anti-D had more than 50 per cent of the  $^{125}\text{I}$ -labelled  $L$  chains in peak 3, but the distribution among the smaller peaks was different in each of these examples.

The rate of dissociation of the antibody from red cells was determined for each antibody<sup>4</sup>, and all were found to be heterogeneous with respect to their rate constants for dissociation. One of the anti-D antibodies was separated by differential dissociation into two fractions, one of the fractions having a high and the other a low average rate constant for dissociation. The electrophoretic distribution (alkaline starch-gel) of the  $^{125}\text{I}$ -labelled  $L$  chains from each fraction was found to be identical.

Although iodination of  $L$  chains is unsatisfactory as a method of trace-labelling owing to the alteration in electrophoretic mobility which it produces, these results suggest that the antibody molecules of a given specificity from different donors are heterogeneous with respect to the

type of  $L$  chains. As IgG globulin molecules each contain only two  $L$  chains, the finding that there were between four and nine different types of  $L$  chains present in the antibodies investigated here suggests that there is also heterogeneity of the structure of antibody molecules within any particular antiserum.

### Ultra-violet Absorption Spectra of Haemoglobins from Various Vertebrates

It is well known that the various vertebrate haemoglobins as well as the individual variants of adult human haemoglobin (Hb A) may be readily distinguished by their different mobility in electrophoresis, adsorbability and stability to thermal denaturation. A possibility of identification, particularly in abnormal haemoglobins, is offered by recombination analysis and, finally, by the determination of the amino-acid composition and sequence. We found the ultra-violet spectrum as recorded between 30,000 and 34,000  $\text{cm}^{-1}$  provided a very simple additional means of differentiation. Little information can be obtained from the literature<sup>1,2,4</sup>. Hb F (foetal human haemoglobin) may be recognized from its well-distinguishable tryptophan band at 34,400  $\text{cm}^{-1}$ , and Matsuda<sup>4</sup> directed attention to the absorption differences between the human  $\alpha$ -,  $\beta$ - and  $\gamma$ -chains. If the ultra-violet spectrum is recorded at high resolution using an appropriate haemoglobin derivative, however, many more differentiated results may be achieved.

Stroma-free haemolysates of red cells, the haemoglobin of which had been oxidized with sodium nitrite and afterwards washed free of plasma and nitrite, served as basic product for the methaemoglobin (Hb(3)) spectrum which is particularly suited for an analysis in the absorption region between 34,000  $\text{cm}^{-1}$  and 30,000  $\text{cm}^{-1}$ . We generally used haemoglobin at a concentration of about  $5 \times 10^{-4}$  val/L. Hb. The concentration was determined by means of the cyanmethaemoglobin absorption at 540 nm. The measurement was carried out with the recording spectrophotometer Unicam SP 700 using the minimum possible slit width. Some results of the measurements are given in Figs. 1a and b.

Each haemoglobin exhibits a specific course of absorption which permits it to be readily identified. This identification may be considerably improved by recording a difference spectrum versus a standard haemoglobin.

In the spectral range investigated, it is, in general, phenylalanine, tyrosine and tryptophan which are respons-

ible for the maximum in the range discussed. Identification of the individual bands observed, with the corresponding amino-acids is feasible. On various other proteins (ribonuclease, lysozyme, pepsinogen and pepsin, chymotrypsin, various albumins) attempts are made to draw conclusions from the location and the height of the bands, particularly in the case of tyrosine, about the

incorporation of the phenol ring of the tyrosine into secondary bindings within the protein<sup>1,2-4</sup>. It is certainly important that under our conditions the fine structure of the phenylalanine band becomes accessible because, in this case, the theoretical interpretation of the effects observed is easier than in the case of tyrosine. Table 1 indicates the shift of the phenylalanine bands in the protein relative to their position in a corresponding amino-acid mixture (the values were taken from a difference spectrum of human Hb(3) versus an amino-acid mixture free of phenylalanine).

The frequency change by about  $200 \text{ cm}^{-1}$ , with the band fine structure maintained, appears to be clear. It demands further investigation, as does the attempt to determine the content of aromatic amino-acids directly by the modified method of Benze and Schmid<sup>5</sup>. The latter method is not directly applicable, as the haem also contributes to the total absorption in the spectral range examined (Table 2 and Fig. 2).

### Anti-cerebroside Antibodies in Cerebrospinal Fluid of Rabbits with Experimental 'Allergic' Encephalomyelitis

In the course of experimental 'allergic' encephalomyelitis (EAE), and after injection of brain emulsions, rabbits produce antibodies against cerebroside<sup>1-4</sup>. These antibodies are demonstrable by the complement-fixation test as well as by the agar-gel precipitation test, when emulsions of cerebroside and the auxiliary lipids, cholesterol and lecithin (CCL), or emulsions of ethanolic extracts from spinal cord, are employed as antigens<sup>5</sup>. By ultracentrifugation and immunoelectrophoresis we were able to identify these antibodies as  $\gamma_{1M}$  (19S) and  $\gamma_2$  (7S) globulins<sup>6,7</sup>. The role of these antibodies in the pathogenesis of EAE is not at all clear<sup>8</sup>. It seemed of interest, therefore, to examine whether anti-cerebroside antibodies are also present in cerebrospinal fluid (CSF) of rabbits with EAE, and to ascertain to which variety of globulin they belong.

Rabbits inoculated intradermally with emulsions of homologous spinal cord incorporated in complete Freund's adjuvant showed severe clinical symptoms of EAE approximately 10-12 days after injection. These animals were killed in the tetraplegic state and CSF was carefully withdrawn from the cisterna cerebello-medullaris after complete exsanguination of the animals. Samples with erythrocyte contamination were discarded. Complement-fixation tests were done as formerly described at  $37^\circ \text{C}$  for both phases of the reaction<sup>9</sup>. The antigens used were emulsions of CCL and of ethanolic extracts from bovine spinal cord. For immunoelectrophoretic examination CSF samples were concentrated according to the method of Mies<sup>10</sup>. 12  $\mu\text{l}$ . of the different CSF pools were electrophoretically separated (200 V, 90 min)<sup>11</sup>. CCL emulsion was allowed to diffuse from the middle channel against the CSF protein fractions. In 8 out of 12 cases equal volumes of the corresponding serum pools were tested on the same slides for comparison.

Antigens applied: OOL emulsion and emulsion of ethanolic extracts from spinal cord (sp.c.); n.t.—not tested.

The protein content of the CSF specimens ranged between 200 and 400 mg per 100 ml., as evaluated by different pools of CSF samples<sup>10</sup>. The normomastix curve dropped deeply in the middle region. In the complement-fixation test we obtained positive results in 8 CSF samples out of 12 pools tested, which were collected from 80 rabbits with acute EAE. The titres ranged between 1/2 and 1/128. Both antigens applied showed about the same reactivity (Table 1). Immunoelectrophoretic examination of the samples showed precipitation in 9 out of 12 cases in the  $\gamma_2$  (7S) globular region. Three of the positive CSF pools precipitated in the  $\gamma_2$  as well as in the  $\gamma_1$  globulin region. The results of the immunoelectrophoretic investigations are summarized in Table 1 and Fig. 1a-c. Control experiments with CSF and serum pools withdrawn from healthy animals gave negative results throughout with both antigens applied.

Similar experiments concerning the demonstration of complement-fixing antibodies directed against ethanolic extracts from rabbit brain were performed by Frick and Scheid-Seydel<sup>11</sup> in 1962. In examining CSF specimens of rabbits with EAE, the authors were able to demonstrate anti-myelin antibodies only in one sample out of 16 tested. It may well be, however, that the discrepancies between Frick's results and our own are due to differences in the sensitivity of the complement-fixation technique applied. It should be stressed that the number of sensitized erythrocytes in the haemolytic system has a great influence on the threshold of sensibility and thereby on the height of antibody titre<sup>12</sup>, in the sense that a higher sensitivity is achieved by applying small amounts of erythrocytes.

Fig. 1. Immunoelectrophoresis of CSF pools and the corresponding serum pools from rabbits with EAE. Anode above, left side: CSF pool, right side: corresponding serum pool; a, No. 6; b, No. 8; c, No. 9 from Table 1; middle channel: OOL emulsion

It is conceivable that the antibody content in CSF is the result of a breakdown of the so-called blood-brain barrier. It would be interesting to see whether these antibodies enter the CSF spaces before any histological alterations typical for EAE are observed, and which type of antibody can primarily be demonstrated. As a contribution to the barrier problem in EAE, time course studies should be performed to find out whether 7S-antibodies are present in CSF earlier than 19S-type antibodies.

HISTOCHEMISTRY

Oxidation of L-Ascorbic Acid by Cells of  
Carcinoma of the Human Cervix

THE increased activity of pentose-shunt dehydrogenases, which had been demonstrated histochemically in cancers<sup>1</sup>, has been partly confirmed by biochemical investigations in carcinoma of the cervix in that the cells of the vaginal secretion gave high values for 6-phosphogluconate dehydrogenase<sup>2</sup>. Since this is said to be an oxidative pathway<sup>3</sup>, attempts were made to test if a concomitant rise in cytochrome oxidase activity could be demonstrated. This was done histochemically, to avoid dilution of active cancer tissue by inactive or necrotic tissue and by stroma. A more intense and permanent histochemical procedure for cytochrome oxidase<sup>4</sup> was applied to sections from eight apparently normal cervixes, three apparently normal endometria, ten primary carcinomata of the cervix and seven other carcinomata of the genital tract. The tissues were removed at operation and were frozen and sectioned by a controlled temperature freeze-sectioning method<sup>4,5</sup>.

The cytochrome oxidase-levels were not elevated in the cancers; in some they seemed somewhat depressed.

An attempt has therefore been made to test whether some system other than that involving cytochrome oxidase, but which also may be capable of reacting directly with oxygen, might show the expected increase in activity. Since it is known that the metabolism of some tissues can alter from one using cytochrome oxidase to one dependent apparently on ascorbic acid<sup>6</sup>, it was decided to test whether changes in the ability to oxidize vitamin C occurred in these malignant cells.

Fresh unfixed frozen sections were incubated for 2 h in a medium containing 0.05 per cent neotetrazolium; 0.05 M L-ascorbic acid; 0.1 M sodium azide in 1 M tris-buffer. Although the pH of the buffer began at 7.6, the pH of the final mixture, once the constituents were dissolved, was pH 5.5. In all the experiments, the pH of the incubation medium was measured immediately before use. The medium was added as a drop covering the section, incubation being in a humidity chamber at 37° C. By this procedure, the sections from histologically normal cervixes showed only very weak reactions, almost exclusively in the basal cells, whereas those from the primary carcinomata of the cervix gave strong to intense deposition of the formazan. It was noteworthy that the cancers produced a clearly stronger reaction in each cell than did the basal cells of relatively normal or even slightly hyperplastic tissue.

This reaction occurred only with the L- and not the D-isomer. It was not given if catechol or phenol were substituted for ascorbic acid in equimolar concentration, nor was it given in the absence of L-ascorbic acid. It was lost if the tissue was stored for longer than 4 days at -70° C. The reaction was totally dependent on the presence of a high concentration of azide, being abolished if the concentration was reduced to 10<sup>-3</sup> M. The addition of potassium cyanide, from 10<sup>-3</sup> to 10<sup>-1</sup> M, appeared to have no effect; nor could cyanide take the place of azide in the normal incubation medium. In the absence of azide, no reaction was obtained until the pH was raised to more than pH 7.0; beyond this value, up to pH 8.5, the amount of formazan deposited increased with the increasing pH of the solution. The response of the tissue at the alkaline range was unaffected by the presence of azide.

Similar, albeit very much weaker, reactions have been obtained with sections of rat liver. The response at the alkaline range was not affected appreciably even when the tissue had been previously immersed in boiling water for 10 min. In contrast, the reaction at the acidic pH values was destroyed by this treatment; it showed optimal activity at pH values of 5.5 or 6.0, being obviously weaker at pH 6.5 and 6.0. In later experiments it has been found that the reaction at the acidic pH is readily inhibited by oxygen.

Consequently, sections of carcinoma of the cervix were incubated in the normal medium in Coplin jars. In some either oxygen or nitrogen had been bubbled through the medium for 10 min prior to immersing the slides. Only a very weak reaction was obtained after oxygenation, and this was completely suppressed when oxygen was passed through the medium also during the incubation. Conversely, enhanced reactions were obtained after the preliminary treatment with nitrogen, and these were further enhanced when nitrogen was passed through the medium continuously during the incubation.

Thus it has been shown that the samples of carcinoma of the cervix studied had a very enhanced ability to reduce neotetrazolium to its formazan in the presence of L-ascorbic acid in acidic solution. The inhibition of this reaction by oxygen suggests that the neotetrazolium is replacing atmospheric oxygen in the oxidation of the ascorbic acid, very much as does methylene blue in the conventional biochemical test for oxidases<sup>7</sup>. That this oxidation is probably enzymatic, in the range of pH values of 4-7, is indicated by the following: first, that it shows

distinct optimal activity at about pH 5.5; secondly, that the activity diminishes with storage, as do the activities of many enzymes studied in tissues frozen in this manner; thirdly, that the activity is destroyed completely by boiling the sections; fourthly, that it depends on the presence of the L-isomer.

One of the prime difficulties of detecting cancer at an early stage has been the fact that the biochemistry of malignancy is characteristically that of loss of apparent chemical activity rather than gain of distinctive properties. The discovery of enhanced pentose-shunt metabolism<sup>1</sup> has already yielded promise that the increased activity may be used for the early detection of certain cancers<sup>2</sup>. It is possible that the establishment of further chemical activities which can be used to characterize malignant growths may assist the early diagnosis of this disease.

## PATHOLOGY

### Attempt to Influence the Increased Solubility of Collagen in Lathyrism by Hydrocortisone

ADMINISTRATION of lathyrogenic agents to growing animals induces a variety of connective tissue malformations such as exostoses, hernias and aneurysms. Some authors claim that it is possible to suppress these malformations of lathyrism by treatment with corticoids, thyroxine and some antirheumatic drugs<sup>1-3</sup>. The basic defect of connective tissue in lathyrism is the alteration of the molecular aggregation of collagen, resulting in increased solubility in acid or neutral salt solutions<sup>4</sup>. In this study an attempt was undertaken to influence the increased solubility of collagen in lathyrism by treatment with hydrocortisone.

For this reason experimental lathyrism was produced in two groups of young rats (initial weight 30 g) by the administration of 60 per cent concentration of sweet-pea seeds (*Lathyrus odoratus*) in the diet for 30 days. One of these groups was treated with hydrocortisone intramuscularly in daily doses of 10 mg/kg. These animals were compared with another two groups of normal rats, one of which was treated with hydrocortisone in a similar manner. The extent of bone changes was checked histologically—the results will be published elsewhere. After 30 days the animals were killed and the dorsal skin was removed, depilated and cut with scissors. In a portion of the tissue the 0.14 M sodium chloride-soluble collagen hydroxyproline was estimated after 24 h extraction at 2° C with occasional vigorous shaking. Dialysable hydroxyproline was assessed after dialysis of a part of this extract against water for 24 h at 2° C; a membrane supplied by Kalle AG., Wiesbaden, was used. Another part of the tissue was extracted with 0.5 M acetic acid for the estimation of

acid-soluble hydroxyproline. These fractions and a sample of the whole skin from each animal were hydrolysed in 6 N HCl at 105° C for 20 h and the hydroxyproline was estimated according to Stegemann<sup>8</sup>.

Table 1 gives the results expressed as  $\mu\text{g}$  of hydroxyproline per 100 mg of dry tissue. It is evident that the animals on *Lathyrus* diet have much higher concentrations of extractable hydroxyproline fractions (neutral and acid soluble). There were high values of dialysable hydroxyproline in lathyritic rats. The treatment with hydrocortisone in intact animals resulted in increased amounts of total hydroxyproline and decreased levels of neutral soluble fraction. This is in good agreement with the results of Smith<sup>6</sup> and those summarized by Kuhn *et al.*<sup>7</sup>. In lathyritic rats the hydrocortisone treatment depressed the elevated amounts of soluble fractions as well as of dialysable hydroxyproline although it did not restore the normal ratio completely.

Table 1

	Total hydroxyproline	Acid soluble hydroxyproline	Neutral salt soluble hydroxyproline	Dialysable hydroxyproline
Control	9 780 $\pm 1 230$	3 660 $\pm 450$	168 $\pm 34$	34.4 $\pm 11.6$
Hydrocortisone	11 160 $\pm 1 370$	4 000 $\pm 780$	109 $\pm 24$	20.8 $\pm 11.7$
Lathyrus	8 390 $\pm 958$	7 000 $\pm 2 180$	2 830 $\pm 615$	3 880 $\pm 543$
Lathyrus + hydrocortisone	10 230 $\pm 1 170$	5 060 $\pm 1 690$	2 010 $\pm 340$	1 590 $\pm 300$

Values indicate statistical average  $\pm$  standard error of the mean.

We suppose that lathyrogenic agents, and hydrocortisone, influence the metabolism of collagen in different ways. It is possible that hydrocortisone promotes the aggregation of collagen molecules, and results in decreased solubility of collagen. In this way hydrocortisone is able to influence the lathyrogenic defect which manifests itself by retardation of collagen maturation<sup>7</sup>. Similar results were obtained when the biological age of lathyritic and hydrocortisone-treated rats was tested by means of chemical contraction and relaxation of tail tendon fibres<sup>9,10</sup>. The possibility cannot be excluded that hydrocortisone inhibits the postulated enzyme which, hypothetically activated by lathyrogens, can sever intra- and inter-molecular cross-linkages<sup>11</sup>.

## IMMUNOLOGY

### Ultrastructure of Antibody-forming Cells

THE method of Jerne and Nordin for demonstrating individual antibody-forming lymphoid cells has been utilized to obtain quantitative information about the cellular changes during antibody formation<sup>1</sup>, to indicate transplantation immunity<sup>2</sup> and to demonstrate antibody-forming cells in 'tolerant' animals<sup>3</sup>. Recently, this method has been combined with autoradiography to investigate the kinetics of antibody formation<sup>4</sup>. In the present studies the plaque method has been used to identify for study by electron microscopy individual cells which have released antibody.

Cell suspensions were prepared from the spleens of rats at various times after intravenous immunization with washed sheep erythrocytes. Dilutions of the spleen cells mixed with sheep erythrocytes in melted agar were poured into Petri dishes over a solidified layer of agar several mm thick. After the overlayer had solidified, the dishes were incubated in a moist chamber at 37° C for 30 min. Antibody released by individual lymphoid cells during this initial incubation diffused out from the cell and became attached to antigenic sites on surrounding sheep erythrocytes. Addition to the plate of 2 ml. of a 1:3 dilution fresh rat serum supplied complement which lysed antibody-coated erythrocytes to produce a clear zone ('plaque') around the antibody releasing (and presumably forming) cell.

Lymphoid cells which produced plaques can be examined before or after staining with various dyes, but this procedure is only partially satisfactory since cells retain their spherical shape and cytological details are poorly demonstrated. However, a disk of agar containing a plaque can be removed from the plate and processed for electron microscopy with reasonable ease.

With the aid of a binocular dissecting microscope at magnification 10–25 times, plaques were punched from the plate using glass capillary tubing 1.2 mm internal diameter. The agar disks were placed on glass microscope slides and examined at magnifications of about 400 times to verify that a single lymphoid cell was present in the centre of the plaque. The disks were fixed for 15 min in buffered glutaraldehyde, washed in phosphate buffer, and post-fixed in buffered osmium for 10 min. Plaques were embedded in 'Epon' or stained with phosphotungstic acid and embedded in 'Araldite'. The disks in plastic were reoriented with the surface of the plaque parallel with the block face. The block mounted in a chuck was brightly transilluminated. A mechanical device mounted on a microscope made it possible to trim accurate block faces about 0.1 mm  $\times$  0.1 mm around the plaque-forming cell. A larger block face showing a plaque-forming cell partially surrounded by a halo of unlysed sheep erythrocytes is shown in Fig. 1. The sides of the trimmed block were perpendicular to the block face making it possible to view the plaque-forming cell from the side of the block. A microscope with a long-focal-length objective mounted to the side and at a right angle to the microtome made it possible to determine precisely the depth of the cell from the block face during sectioning. Using these procedures,

Fig. 1 'Epon' block containing a plaque with a central antibody-releasing cell. The trimmed block face measures 90  $\mu$   $\times$  120  $\mu$ . This block is ready for serial sectioning for electron microscopy.

Fig. 2. Electron micrograph of plaque-forming cell from rat spleen. Rough-surfaced endoplasmic reticulum is abundant. The cell nucleus is not in the plane of sectioning. ( $\times$  9,500)

sections of plaque-forming cells could be regularly obtained. 'Epon' sections were stained with uranyl acetate or lead hydroxide or a combination of the two stains.

A representative example of plaque-forming cells is shown in Fig. 2. The abundant, rough-surfaced endoplasmic reticulum is filled with finely granular material. The nucleus, not seen in all sections, usually contains chromatin material coarsely clumped on the nuclear membrane. Most of the plaque-forming cells have morphological characteristics of plasma cells. Scattered vacuoles of various types in the cytoplasm may be normal cell components or may represent changes of focal cytoplasmic degradation resulting from the rather long interval (up to 45 min) between removal of the spleen and fixation of the developed plaque. However, fine structural details of the endoplasmic reticulum and the mitochondria are preserved, suggesting that cellular morphology is not seriously damaged by the *in vitro* manipulations.

It is not known whether plaque-forming cells release one or several molecular types of anti-sheep erythrocyte antibody. Droplets of purified fractions of either 19S or 7S antibody produce haemolysis of sheep erythrocytes in agar plates, indicating that cells releasing sufficient quantities of either type of antibody would be capable of producing plaques. An exponential increase in the number of plaque-forming cells occurs during the first 4 days after immunization and only 19S antibody is detectable in serum on the fourth day after immunization. Unquestionably, plaques are formed by cells releasing only or predominantly 19S antibody. Spleens of rats killed 4 days after repeated twice-weekly antigen injections contain about 10-fold fewer plaque-forming cells than spleens of animals killed 4 days after a single antigen injection\*. Serum from the repeatedly injected animals had high concentrations of both 19S and 7S antibody. Presumably some plaques obtained from animals receiving repeated antigen injections might contain cells which had released only or predominantly 7S antibody. Up to the present, electron microscopy has not revealed ultrastructural differences in plaque-forming cells from animals in the early primary response when compared with cells obtained from animals receiving repeated antigen injections.

In an attempt to identify the type of immunoglobulin released by cells, plates containing plaque-forming cells were treated with 2-mercaptoethanol. Droplets of serum fractions containing 19S antibody placed on agar plates were inactivated by this treatment while droplets contain-

ing 7S antibody were not. 2-Mercaptoethanol inactivated about the same proportion of plaques in plates prepared from animals in the early primary response as in plates prepared from animals receiving repeated antigen injections.

The foregoing results indicate that plaques are formed by cells in the phase of rapid synthesis of antibody and this phase of synthesis is probably concomitant with synthesis of 19S antibody. However, the results do not exclude the possibility that some plaques were produced by cells synthesizing predominantly 7S antibody. The studies are not sufficient to indicate whether different cell types produce 19S and 7S antibody or whether synthesis of 19S antibody represents only a phase of antibody production by a single cell type. Recent evidence indicates that lymphoid cells usually contain only 7S or 19S immunoglobulin but that some may contain both types\*. No correlation could be made, however, between the morphology of cells and the type of immunoglobulin produced.

In previous investigations of the ultrastructural characteristics of antibody-forming cells ferritin was used as the immunizing antigen\*. The experimental manipulations which are necessary to allow ferritin to penetrate an antibody-containing cell often result in structural alteration. Also, this method indicates only that a given cell contains specific antibody; it furnishes no information about the ability of the cell to release antibody at that time. The plaque method developed by Jerne makes it possible to examine the ultrastructure of cells which have actively released antibody; metabolic activity is required for the development of a plaque<sup>1</sup>.

Electron microscopy of plaque-forming cells together with electron microscopic autoradiography will provide essential information about the morphology of specific antibody protein synthesis.

### Assay of Insulin Antibodies produced by the Guinea-pig

The antigenic properties of insulin are now well recognized, but no simple method has yet been described for the routine detection and assay of insulin antibodies. The method described here is based on the classical observation by Berson, Yalow, Bauman, Rothschild and Newerly<sup>1</sup>. They showed that during chromatoelectrophoresis on filter paper, <sup>125</sup>I-labelled insulin bound by insulin antibodies in human serum moves with the  $\beta$ - $\gamma$ -globulins, while free insulin remains fixed at the point of application of the serum-insulin mixture on the filter paper. When an excess of unlabelled insulin mixed with a trace of labelled hor-

more is added to the anti-insulin serum, the excess insulin is adsorbed from solution by cellulose and the amount bound by the antibodies is measured in the supernatant solution. We have used this assay system for serum obtained from guinea-pigs treated with bovine insulin<sup>4</sup> and capable of neutralizing insulin at rates ranging from 0.1 to 3.5 units per ml. serum. It can, however, be adapted for the detection and assay of antibody concentrations lower than this; it has not yet been used for anti-insulin sera of other animals or of man.

Anti-insulin serum (0.1 ml.) diluted in phosphate buffer (0.4 ml.; 0.1 M, pH 7.0) is placed in a centrifuge tube to which is then added a mixture of unlabelled bovine insulin (0.6 u.) and a trace of <sup>125</sup>I-labelled insulin (approximately 1 m.u.; 3–10 mc./mg insulin; Abbott Laboratories, Oak Ridge, Tennessee) dissolved in the same volume (0.5 ml.) of buffer. The reaction is allowed to take place at room temperature for 30 min; it is actually complete within a minute. Then a suspension of cellulose in the same buffer (1.0 ml.; 10 per cent w/v; 'MN' cellulose powder, Mecharey, Nagel and Co., Duren, Germany) is added and the mixture shaken intermittently for a further 30 min; again much shorter times are needed. The cellulose is deposited by centrifugation and the supernatant solution (1 vol.) added to Bray's<sup>5</sup> solution (10 vols.) in which the  $\beta$ -emissions are counted in a liquid scintillation counter (Packard Instrument Co., La Grange, Illinois).

In the presence of the same insulin mixture, more than 98 per cent of the added radioactivity was recovered from the supernatant solution when an excess (0.5 ml.) of an undiluted sample of anti-insulin serum was added (Lot 302). Part of this radioactivity (3–8 per cent) was recovered from the supernatant solution when an equal volume of normal serum was used in place of the anti-insulin serum; this probably represents degraded fragments of the labelled hormone and insulin bound non-specifically by the serum proteins. The difference between these two values, or between counts recovered from equal aliquots of supernatant solution under the same conditions, is therefore proportional to the total amount of insulin added initially. Between these two extremes, as shown in Fig. 1, a linear relationship ( $r = 0.971$ ;  $P < 0.001$ ) was found between the volume of anti-insulin serum added and the counts recovered from aliquots of the supernatant solution, but towards the point of neutralization this relationship ceased. Provided an adequate excess of insulin is present, therefore, the potency of a serum sample can be determined from the

Fig. 1. Percentage of added radioactivity recovered from the supernatant solution after treatment of variable volumes of anti-insulin (closed circles; Lot No. 302) and normal (open circles) guinea-pig sera with a constant amount of bovine insulin (600 m.u.) and a suspension of cellulose. Each point represents the mean ( $\pm 2 \times S.D.$ ) of 5–15 observations. For reasons given in the text, radioactivity recovered using an excess of anti-insulin serum (0.5 ml.) is taken to be 100 per cent

Guinea-pig serum (Lot No.)	in vitro Serum potency	in vivo
196	2.62 $\pm$ 0.3 (13)	2.3
271	1.5 (2)	1.5
301	2.4	2.0
302	1.66 $\pm$ 0.2 (10)	1.5
311	2.0 (2)	1.0
317	2.3 (2)	1.6

Each serum was assayed *in vitro* by the present method and *in vivo* by the method of Armin *et al.* (ref. 4). Mean potencies ( $\pm S.D.$ ) are stated as units bovine insulin neutralized or bound by 1.0 ml. serum, where more than one assay was carried out the number is shown in brackets.

counts obtained from a portion of the supernatant after addition of the cellulose suspension: units insulin bound by serum sample equals:

$$\frac{\text{c.p.m. sample} - \text{c.p.m. blank}}{\text{c.p.m. excess anti-insulin serum} - \text{c.p.m. blank}} \times \text{units insulin added}$$

For any sample of anti-insulin serum assayed an equal volume of normal serum was used as a blank. The volume of normal serum, within the range used here (0.1–0.5 ml.), had little effect on the radioactivity recovered from the supernatant solution which seldom exceeded 10 per cent of that recovered using an excess of anti-insulin serum.

The results obtained by this method, as shown in Table 1, are comparable with those found by the much cruder and less accurate method described previously; potency was then related to the hyperglycaemic response of rats injected intravenously with the serum<sup>4</sup>. From results obtained over a period of 9 months, guinea-pigs were separated into distinct groups according to their ability to produce insulin antibodies. After 4–5 monthly injections of insulin the good producers consistently yielded serum neutralizing 1.5–5.5 u. insulin/ml.; while the poor producers, a very variable proportion, yielded serum neutralizing less than 0.5 u./ml.

Although primarily designed and used to assay these potent sera, the method can be adapted to assay insulin antibodies in much lower concentrations. Thus, by reducing the amount of added insulin, it has been used to assay free antibody concentrations in animals (dogs and rats) injected with guinea-pig anti-insulin serum; normal sera from these animals did not interfere with the assay. Serum samples neutralizing 10–0.1 m.u. insulin have been successfully assayed.

Finally, we would emphasize the empirical nature of this method. Guinea-pig anti-insulin serum contains more than one antibody to insulin and these may have differing insulin-binding capacities. A more accurate and meaningful method of assay will not emerge until homogeneous antibody preparations have been isolated. Meanwhile, this method has proved successful in investigations of the production of insulin antibody in guinea-pigs and should facilitate preliminary analysis of the basic characteristics of the antibody itself.

We thank Prof. R. H. S. Thompson and Guy's Hospital Medical School, London, for assistance in the production of most of the anti-insulin serum used here; the National Institutes of Health for a grant (AM-7211); the Agency for International Development for a fellowship (L. R.-C.); and Mr. L. Norman for assistance.

## RADIOBIOLOGY

## Fading in Thermoluminescent Lithium Fluoride used for Radiation Dosimetry

LITHIUM fluoride powder is now being used extensively for thermoluminescent dosimetry of ionizing radiations because of its good tissue-equivalence with respect to photon energy, and its reported absence of fading<sup>1-3</sup>. We have found hitherto unreported changes of response with time, predominantly manifested by fading of the read-out by some 10-20 per cent at 3 weeks after irradiation, followed by a tendency to increase towards the initial value at 6-8 weeks. This fading can cause difficulties in practical use unless care is taken to read-out specimens at the same time after irradiation. The fading reported here is other than any occurring in the first 24 h.

We have used commercially available lithium fluoride dosimetry powder, type 'TLD-100' (Harshaw Chemical Co., agents Nuclear Enterprises (G.B.) Ltd., Edinburgh) purchased in several batches between January 1963 and February 1965, and 'type N' (Controls for Radiation, Boston, Massachusetts) from another commercial source. These two types of powder are expected to be similar, and different in composition from TLD-700 and type 7, which we have not tested for fading. Successive exposures followed by annealing for re-use of a given batch of powder result in appreciable changes of sensitivity<sup>4,5</sup>, although the radiation-induced glow peak apparently remains a single peak. Batch-to-batch reproducibility is therefore poor, as is well known, but within one annealed batch the readings are repeatable to within 1-3 per cent. Four different read-out devices were used in these experiments: two were built in our laboratories<sup>6</sup>, while two others are commercially available. The results should therefore not be a function of unusual optics or heating cycles in the read-out apparatus. All four readers measured the integral of the glow curve.

The experimental procedure was to irradiate a capsule containing 1-2 g of LiF powder to usually 1,000 rads, using 15-MeV electrons, 15- or 5-MV X-rays, or cobalt-60  $\gamma$ -rays (with appropriate build-up material, and with subsequent mixing of the powder, to avoid any non-uniformity of dose). The powder was stored in the dark at room temperature unless otherwise stated. One experiment showed that fading was closely similar for doses of 5, 50, 500 and 5,000 rads. At appropriate times after irradiation, 4-9 read-outs using 30 mg of powder each were made for every time point. In some experiments the powder was divided into two parts for a comparative

Fig. 1. Measurements of TLD-100 response versus time. Doses of 1,000 rads were given and the powder was stored in the dark at room temperature unless otherwise indicated on the curves, except for the upper pair which are for 100 r. exposure and storage at 24° C (dashed) and -18° C (full line). Month and year of irradiation are given for each curve.

Fig. 2. Fading of LiF given 1,000 rads and stored in the dark at room temperature before read-out. Lines: TLD-100. Dots: Type N phosphor (believed to be similar in composition).

experiment, for example (1) stored in the dark or behind glass exposed to sunlight; (2) stored at 37° C or at room temperature; (3) stored at -18° C or at room temperature; (4) read-out on a laboratory-constructed or a commercial reader. In each such paired experiment the agreement between the two fading curves was within  $\pm 2$  per cent.

Fig. 1 shows eleven curves of response versus time, obtained between June 1963 and July 1964, except for the upper pair at 24° C and -18° C after 100 rads which was obtained in April 1965. During these experiments it was found that the radioactive light source (with  $\text{CaWO}_4$  phosphor) used to standardize the photomultiplier gain was somewhat temperature dependent (that is, 1 per cent decrease in light intensity for 1° C increase in temperature). The nine curves in Fig. 2 have been obtained with precautions to avoid errors due to this variation. We therefore attach most weight to the results in Fig. 2; but the results in Fig. 1 support them.

Fading appears to be independent of dose from 5 to 5,000 rads, and depends less on temperature of storage (between 37° C and -18° C) than on the particular batch, as shown by the pairs of curves in Fig. 1. In three curves a rise of response was seen by about 3 weeks, without a large initial fading, this rise corresponding to the rising part of the other curves in magnitude and in time. Two of the fading curves in Fig. 2 are for the Type N phosphor (dotted) and the results are similar to those for TLD-100. Thus in each of twenty fading curves, obtained at different times over a period of two years, a change of at least 10 per cent was observed during a period of 3 weeks after irradiation.

The temperature of annealing was investigated (nominally 400° C for 1 h, followed by 80° C for 24 h as proposed by Cameron *et al.*<sup>7</sup>). Fading was not eliminated if the temperature was somewhat less than 400° C. The effect of raising it to 420° C, say, or of prolonging the time to 1.5 h was not investigated. No differences were observed when the powder was allowed to cool to 80° C overnight instead of transferring it at 1 h to 80° C.

If the later increase of response often brings the readings close to the initial values, an explanation is provided of the fact that this fading has not been reported by other workers. The results recorded here are, however, consistent with the "absence of fading within  $\pm 7$  per cent" recently reported by Boone, Crosby and Shalek<sup>8</sup>. It is possible that readings taken at 3-, 6- or 12-months intervals would show little change from the initial readings<sup>9</sup>. We have not investigated the accuracy of this recovery to the initial value because each fading experiment requires a relatively large quantity of powder.

Such fading and recovery could be explained in principle by three levels of energy storage, sequential in time, from the second one of which significant optical transitions did not occur on heating for read-out.

It is to be hoped that a solution can be found, and the fading avoided, by different annealing, by pre-heating immediately before read-out, or by reading peak-height instead of area under the glow curve\*. Either of the last two solutions would require a more complicated control of the heating cycle than is generally used. We wish to emphasize that we have only investigated TLD-100 and Type N LiF.

We thank M. Levitt, M. West and Angela Deubert for their assistance, and Prof. J. Rotblat for the use of facilities. J. F. Fowler thanks the Medical Research Council for a grant. C. J. ## BIOLOGY

### An Inhibitor of Plant Growth-produced by *Aspergillus wentii* Wehmer

In the course of an empirical screening programme we found that culture filtrates of *Aspergillus wentii*, grown on Raulin-Thom medium (5 per cent glucose) supplemented with 0.1 per cent Difco yeast extract, have a pronounced inhibitory effect on the growth of 'Meteor' pea seedlings. When seedlings were sprayed to run-off with undiluted culture filtrate, shoot growth almost ceased for a week and then recommenced slowly. Newly formed internodes were abnormally short; leaflets were very narrow, in extreme cases becoming almost linear; flowers were similarly reduced, being almost apetalous; there was a marked loss of apical dominance, several axillary buds producing dwarfed branches. Newly formed stems and leaves were markedly chlorotic. This abnormal growth persisted throughout the subsequent life of the plants. The leaves sprayed, but not those formed after spraying, developed necrotic spots.

The growth-inhibitor was eventually extracted and shown to be 1-amino-2-nitrocyclopentane-1-carboxylic acid<sup>1</sup> (I), referred to hereafter as ANCPA.

(I)

**Effects on plants.** ANCPA produces effects on peas like those described here when sprayed on at 20 µg/ml., by application of 10 µg/plant in a 0.02 µl. microdrop to a single leaf, or by injection of 1 µg into the stem. It causes no necrosis; that observed in preliminary experiments was due to some other constituent, extractable by charcoal, of crude culture filtrates. It has a similar but even more marked effect on dwarf beans (*Phaseolus vulgaris*) and, if bean or cucumber seeds are soaked in solutions of ANCPA (10 µg/ml.) and then transferred to germination chambers, though percentage germination is not reduced, hypocotyl and radicle extension are much reduced. It inhibits extension of lettuce hypocotyls in seedlings growing on filter paper moistened with an aqueous solution, particularly under conditions where growth is maximal in controls, for example in darkness or in white light if gibberellic acid (GA) is supplied in addition\* (Table 2). Surprisingly, ANCPA does not appreciably inhibit extension of pea stem sections or pea root sections, or expansion of bean leaf disks, in buffer-sucrose with or without optimal indolyl-3-acetic acid, but it does inhibit extension of excised pea buds (Table 1) in a medium containing kinetin and gibberellic acid\*.

Table 1. FINAL LENGTH (MM) OF PEA BUDS (Five days growth in buffer/sucrose, in light at 16° C; mean of 20 replicates)

ANCPA µg/ml.	Basal medium	+ Kinetin (2 µg/ml)	+ Gibberellic acid (1 µg/ml)	+ Kinetin and GA
0	4.6	6.2	7.0	10.3
0.01	5.0	5.8	7.8	11.7
0.1	4.7	6.4	7.3	9.7
1.0	4.0	4.6	7.0	5.2
10.0	2.4	2.8	2.9	2.8

Significant difference ( $P=0.01$ ), 0.8

The observations described here do not distinguish between effects on cell division and on cell extension. ANCPA markedly reduces the rate of mitosis in root tips of several species, especially pea (*Pisum sativum*) (Table 3).

In connexion with the chlorosis of plants treated with ANCPA, it is significant to find that at 1 µg/ml. it reduces, and at 100 µg/ml. prevents, chlorophyll synthesis in sections of etiolated wheat leaves exposed to light. It does not delay (op. kinetin) or accelerate senescent chlorophyll loss in sections of light grown wheat leaves.

**Reversal of L-leucine.** Various lines of thought made it seem possible that ANCPA might be acting as an amino-acid antagonist. Of thirty amino-acids and related compounds tested, only L-leucine, and to a lesser extent L-methionine, would reverse the effects of ANCPA on lettuce hypocotyl extension (Table 2); D-leucine and D-methionine were ineffective. Considerable excess of

Table 2. FINAL LENGTH (MM) OF LETTUCE HYPOCOTYLS (Mean of 30 replicates)

ANCPA µg/ml.	Growth in light*			Growth in darkness		
	0	L-Leucine (µg/ml.) 0.25 25.0	100.0	L-Leucine (µg/ml.) 0 100		
0	24.5	25.7	25.0	25.5	24.6	24.1
1	15.3	14.4	16.5	23.7	22.8	24.5
2	13.6	15.1	16.3	21.7	17.2	24.9

Significant difference ( $P=0.01$ ) 2.7

2.1

\* In presence of 10 µg/ml. gibberellic acid.

L-leucine was necessary to reduce the effects of ANCPA appreciably in this experimental system. Similar leucine excess is needed to reverse ANCPA inhibition of root growth of cucumbers or cress seedlings, and it has not been found possible even partially to reverse the inhibition of pea bud growth or growth of intact pea or bean shoots. ANCPA also greatly reduces the rate of multiplication of yeast cells at 20 µg/ml., but this effect is only partially

reversed by a 100 times equimolar concentration of L-leucine.

The effects of ANCPA on mitosis in pea-root tips, on the other hand, can be reversed by very low concentrations of L-leucine. The effect is apparently not competitive (Table 3).

Table 3. NUMBER OF MITOTIC FIGURES PER 1,000 NUCLEI IN PEA ROOT TIPS  
(24 h after treatment with ANCPA)

ANCPA ( $\times 10^{-4}$ M)	Exp. 1 L-Leucine ( $\times 10^{-4}$ M)		Exp. 2 L-Leucine ( $\times 10^{-4}$ M)			
	0	7.6	0	1.5	3.0	6.0
0	92	100	118	—	—	—
0.06	14	90	—	—	—	—
0.6	0	83	—	—	—	—
3.0	0	121	0	18	77	92
30.0	—	—	0	—	—	126
						155

Thus, in some experimental systems at least, ANCPA is a well-defined leucine antagonist. In this connexion its effect on *Nicotiana* plants is interesting. Doses of 10  $\mu$ g/plant injected into the apical buds of young rosette-stage plants delayed stem formation and induced production of narrow, strap-like leaves with pronounced interveinal chlorosis, with increased development of lateral shoots. This closely simulates the physiological condition known as frenching<sup>1</sup>, which can also be simulated by feeding seedlings with isoleucine or *alloisoleucine*<sup>2</sup>. A number of synthetic analogues of ANCPA, including 1-aminocyclopentane-1-carboxylic acid and 1-aminocyclohexane-1-carboxylic acid, have also recently been shown to be amino-acid antagonists<sup>3-5</sup>.

It is not possible at present to characterize the effects of ANCPA on plant metabolism more closely, but it is noteworthy that 2-thiouracil induces comparable morphogenetic changes in *Cannabis*<sup>6</sup> and that this has been interpreted<sup>7</sup> as an inhibition of protein synthesis due to a disturbance of RNA metabolism.

### Cation-anion Ratios of Plants

Dijkshoorn<sup>1</sup> has recently summarized the results of many analyses for the total equivalents of metals (potassium, sodium, magnesium, calcium) and non-metals (nitrogen, phosphorus, sulphur, chlorine) in *Lolium perenne*, and has calculated the balance of acidity within the plant following on the higher intake of non-metals as anions. From the content (in equiv./kg) of metals as 1.8 and non-metals as 3.2 he concludes that internal acidity must have risen by 1.4, but that this is more than offset by the reduction of nitrate and sulphate, both of which consume acid. If the reduction of nitrate is written as  $\text{HNO}_3 + 8\text{H} \rightarrow 3\text{H}_2\text{O} + \text{NH}_3$ , one obtains a disappearance of 1 or 2 protons per nitrogen reduced, according to whether one treats  $\text{NH}_3$  as a neutral molecule (as Dijkshoorn does) or as an alkali.

This calculation suggests a comparison with the effect on internal acidity of absorbing ammonium ion from solution. For every atom of nitrogen absorbed as  $\text{NH}_4^+$ , one proton disappears from the plant; for every atom absorbed as  $\text{NO}_3^-$  one proton appears in the plant, but the reduction of this ion to ammonium absorbs two protons, so that the net internal effect so far is the same for both forms of nitrogen. However, when the intake of other nutrients is considered, the two forms affect the internal acidity differently. Both these ions in glasshouse cultures are absorbed more rapidly than any others, so that  $\text{NH}_4^+$  cultures become acid and  $\text{NO}_3^-$  cultures become alkaline. But if we calculate the non-nitrogenous ions from such results as those of Cole *et al.*<sup>2</sup>, we find that there remains a net excess absorption of cations in both cases, but far stronger for  $\text{NO}_3^-$  than for  $\text{NH}_4^+$  cultures (Table 1). Thus the nitrate plants consume a greater net total of internal acidity than do the ammonium plants.

Table 1. CONTENT OF MAJOR NUTRIENTS IN PLANTS GROWN IN CULTURE SOLUTION

(Cole <i>et al.</i> ) (in equiv./100 g fresh weight)			
		Nitrate cultures	Ammonium cultures
Maize	Nitrogen as anion	45.0	—
	P, S, Cl	11.9	15.5
	Nitrogen as cation	—	49.0
	K, Ca, Mg	24.5	20.4
	Excess non-N cation	13.6	4.9
Tomato (young leaves)	Nitrogen as anion	55.1	—
	P, S, Cl	11.2	12.1
	Nitrogen as cation	—	75.6
	K, Ca, Mg	40.0	18.6
	Excess non-N cation	23.8	1.5

One may use these results also in considering the doctrine of a constant ratio of metals to non-metals in plants<sup>3</sup>. This has been dealt with by Cunningham<sup>4</sup>, who pointed out that the ratio of metals to non-metals in Italian rye-grass in Britain ranged from 0.33 to 0.93. If the foregoing doctrine rests on the idea that plants absorb cations at about half the rate of anions, then it is opposed by the work just quoted<sup>5</sup> where plants in ammonium cultures absorb cations four times as rapidly as anions. In Cunningham's plants grown with heavy doses of ammonium sulphate, the ratio of metal to non-metal (unfortunately quoted by him as cation-anion ratio) was the lowest of all at 0.33; but the true cation-anion ratio may have been the highest of all since much ammonium was probably absorbed as such. As a further point against the belief in a constant ratio, anion uptake has a higher temperature coefficient than cation uptake<sup>6</sup> and Cunningham's value of 0.93 for winter fits this last-mentioned relation.

### Genesis of Ethylene in Apples

EYMER since Kidd and West<sup>1</sup> showed that emanations from ripe apples stimulated unripe apples into the respiration climacteric, and Gane<sup>2</sup> proved that the active principle in these emanations was ethylene, search has been made for the origin of this 'ripening hormone'. The search has been intensified in the past few years. Burg and Thimann<sup>3</sup> state that "there is general agreement that ethylene production is restricted to the stage in the life of fruits during which ripening occurs". They were unable to decide precisely the source of the ethylene, but suggested that it may be produced by the mitochondria. Later Burg<sup>4</sup> concluded that the biosynthetic source of ethylene is not to be found in intermediates of glycolysis, acid metabolism

Fig. 1. Ethylene production and respiration rate (carbon dioxide output) of whole fruit, and lipoxidase activity of the peel of 'Cox's Orange Pippin' apples, picked at two stages of development and stored at 12° C ('off tree') and during development ('on tree'). The figures for ethylene production are taken, with the author's permission, from Wilkinson (ref. 9)

or the direct oxidation pathways of sugars, although it may be formed fairly directly from sugars by an, as yet, unknown pathway. More recently, Burg and Burg<sup>4</sup>, using <sup>14</sup>C-labelled, possible precursors of ethylene and apple tissue, concluded that, although ethylene formation is related to the metabolism of Krebs cycle acids as suggested by Wang *et al.*<sup>5</sup>, the relationship does not appear to be a direct one.

Lieberman and Mapson<sup>6</sup> have very recently described a model system which produces ethylene from the unsaturated fatty acid linolenic acid, after activation in various ways including the action of lipoxidase, in the presence of cuprous ions. They suggest that *in vivo* in apples cytoplasmic particles, lipoxidase and a copper enzyme might form a system for the biogenesis of ethylene.

Over the past few years we have been studying the enzymatic systems of senescing apples with special reference to the respiration climacteric. We have found that lipoxidase (determined by a modification of the method of Surrey<sup>7</sup>) appears, especially in peel tissue, during the early climacteric period and increases very rapidly during the course of the climacteric whether this occurs in detached fruit stored at 12° C or in fruit remaining attached to the tree. Wilkinson<sup>8</sup> has investigated the production of ethylene during the development of the climacteric in apples, and in Fig. 1 we have superimposed some of his results on our own for the respiration of whole 'Cox's Orange Pippin' apples and the lipoxidase contents of the peel from similar apples picked at approximately the same time as Wilkinson's apples. The form of the curves for ethylene production and lipoxidase activity in storage is strikingly similar, and increase in lipoxidase activity commences just before the onset of ethylene production and the climacteric. During the development of the climacteric on the tree, increase in lipoxidase activity precedes the appearance of 'measurable' quantities of ethylene. Kidd and West<sup>10</sup> have suggested that the longer time required for the climacteric rise to be attained on the tree is probably due to a greater degree of ventilation in the orchard rather than to a decreased rate of ethylene production.

Burg and Thimann<sup>4</sup> used pulp as well as, presumably, peel tissue in their experiments on ethylene production; we have found that in the pulp tissue also lipoxidase increases during the climacteric period, although the highest values attained are less than one-tenth those in the peel. Meigh<sup>11</sup> has found that ethylene production by the peel of apples is several times as great as that of pulp tissue. In our experiments lipoxidase activity is present in the soluble fraction, and our mitochondrial fraction<sup>12</sup> contains, at the maximum value of overall lipoxidase activity, only one-thirtieth the activity of the 'supernatant' fraction.

One of the most obvious phenomena associated with the climacteric in certain varieties of apples is the development of an oily coating on the skin. The object of this communication is to direct attention to the fat metabolism of the apple as a possible source of ethylene and to suggest that some at least of the enzymes involved in the process are outside the mitochondria. This is in line with Burg's<sup>4</sup> suggestion of a 'fairly direct' route from sugars.

It is suggested that one of the functions, but not necessarily the only one, of lipoxidase is related to the biogenesis of ethylene. Perhaps of relevance here is the recent finding by Freeman<sup>13</sup> that the diene-hydroperoxides found during the action of lipoxidase on unsaturated fatty acids can be decomposed by cytochrome-c.

## Antibiotics as a Means of Control of Bacterial Contamination of Storage Tissue Disks

DURING the investigation of metabolism of storage tissues of higher plants, it is common to wash and aerate disks of the tissue for periods of several days or weeks. To this end, a variety of techniques has been reported, but in most cases it was not possible to impose rigorous conditions of sterility, although, in analysing the behaviour of tissues treated in this way, it is evidently necessary to ensure that the presence of micro-organisms is not a significant factor. The experimenter has usually used such criteria as retention of pigment if any, maintenance of turgor, and clarity of the suspending liquid. Recently, Bacon, MacDonald and Knight<sup>1</sup> have shown that these criteria may be observed even when substantial contamination of disks by bacteria has occurred, and they found that disks (1 cm diam. and 1 mm thick) of sugar beet showed the presence of about  $3 \times 10^7$  organisms/disk after washing for 4 days. During a programme of research into enzyme synthesis in storage tissue disks<sup>2,3</sup> we have

found that artichoke and carrot disks become contaminated with bacteria to a similar degree, ranging from  $5 \times 10^4$  per disk after 24 h to  $4 \times 10^7$  after 3 days.

Using standard microbiological techniques we have identified micro-organisms which occur on disks of carrot and artichoke, and under our conditions of washing we found only Gram-negative bacilli of the pseudomonad type, for example, *Pseudomonas fluorescens*, *Achromobacter anophage* and *Achromobacter parvulus*; on no occasion was fungal contamination found. Bacon *et al.* imposed sterile conditions in their experiments, but although this is obviously the ideal circumstance it is difficult to achieve consistently and entails considerable labour. Some other workers have used antibiotics, but in assessing their effectiveness they appear to have used the same criteria as above; penicillin (10–50 µg/ml.) has been commonly used, but as it is active primarily against Gram-positive bacteria, it would not seem to be a suitable choice, as soil organisms, the most likely contaminants of storage tissues, are largely Gram-negative. Streptomycin is sometimes used alone (10–50 µg/ml.), or together with penicillin; in neither case does the controlling action appear to have been assayed directly by bacterial counts.

In order to discover suitable controlling agents, we considered it necessary to investigate more directly the effect of these and other antibiotics, and our results show that penicillin and streptomycin are useless under our conditions; the only effective antibiotic, of twelve tested, was chloramphenicol.

These results may be of interest to other workers in the assessment of means of controlling bacterial contamination of storage tissue disks.

Penicillins (potassium salts of penicillins V and G, sodium benzylpenicillin G, ampicillin), dihydrostreptomycin, chloramphenicol, tetracycline, neomycin, terramycin, erythromycin, novobiocin, kanamycin, polymixin, fusidic acid and methicillin were tested for action against the isolated bacteria (4 species) in pure culture using Difco 'Bacto Sensitivity Disks' (Baird and Tatlock, Ltd.) which enable the effect of antibiotics at low concentrations to be determined. Those which were effective by this test, namely, dihydrostreptomycin, chloramphenicol, neomycin, kanamycin, and also the penicillins (which were not effective) were added at various concentrations to the medium at the onset of washing disks: the effects on the growth of the bacterial population are given in Table 1 and the

corresponding effects on a metabolic process of the plant tissue, namely, invertase development, are also given. Chloramphenicol appears to be the only satisfactory compound, as at low concentrations it inhibits bacterial growth to insignificant numbers while not affecting the metabolic processes under investigation; at much higher concentrations, however, it does affect the enzyme development, as might be expected from a known inhibitor of protein synthesis. These conditions must obviously be established for each individual case, but we have found that chloramphenicol at concentrations of 50 µg/ml. has no detectable effect on a range of metabolic activities studied in storage tissues during the washing process. It is noteworthy that the penicillins had no effect in reducing bacterial contamination at the concentrations used, and furthermore they markedly affected invertase development.

We thank Miss Paula Reed for advice regarding microbiological techniques, Bayer Products for a gift of kanamycin sulphate ('Kannasyn'), and Glaxo Ltd. for gifts of penicillins V and G. We also thank the Royal Society for an equipment grant.

### Transpiration as related to Internal Water Content

THE valuable concept of water movement through plants as a catenary process<sup>1</sup> explicitly assumes no change of plant moisture content. While this assumption is adequate for many purposes, the quantities of water within larger plants are considerable, and variation over a period of time may be important. From Ovington's<sup>2</sup> results for plantations in southern England, the moisture content of the aerial parts of the trees (expressed as the equivalent depth of water) averaged 3.3 in., with a maximum value of about 7 in. (47-year-old *Picea abies*). The needles of young *Pinus sylvestris* in pots well supplied with water had a variation over a 24-h period in summer amounting to 5 per cent of the saturated moisture content<sup>3</sup>. If similar fluctuations occur in larger trees in the field, these would amount to 0.05 in. of water or 1 l./tree at 2,000 trees/ha. in a total water content of the canopy of 40,000 kg/ha. When the soil moisture tension in the experiment with potted pines exceeded an atmosphere, internal drying of the leaves occurred and the lost water was not replaced during the night. Should the moisture tension of soil of the rooting zone in a plantation reach the wilting point, perhaps as much as another 0.1 in. of the canopy moisture might be lost if the leaf water deficits were similar to those for the potted trees.

Probably the best available data on seasonal variation of the moisture content of tree boles are the measurements of Clark and Gibbs<sup>4</sup>, though their methods leave much to be desired<sup>5</sup>. The North American species examined showed, on the average, a seasonal fluctuation of the sapwood moisture content of 40 per cent on a dry-weight basis. The heartwood variation averaged about 15 per cent. The drying of the wood was achieved in approximately 100 days. Comparing these measurements with Ovington's<sup>2</sup> figures for the same genera but different species, it seems possible that a net loss of 0.5 in. or more of internal water could occur by transpiration in the summer.

These highly approximate estimates at least show that the available portion of the internal water content of plants is appreciable and may be quantitatively similar to

Table 1. EFFECT OF VARIOUS ANTIBIOTICS ON BACTERIAL CONTAMINATION AND INVERTASE DEVELOPMENT OF CARROT TISSUE DISKS

Antibiotic	Concentration (µg/ml.)	Bacteria/disk	Invertase development as percentage water control
None (0 h)	—	<10 <sup>3</sup>	—
None (24 h)	(Water control)	$6.2 \times 10^4$	100

	100	$9.1 \times 10^3$	100

Disks 1 cm diam. 1 mm thick were agitated by passing a stream of filtered air through the washing solution (1 disk/2 ml.), maintained at 25° C for 24 h.

For invertase assay disks were transferred to 0.025 M sucrose (1 disk/1 ml.) and reducing sugar was estimated after 1 h. For bacterial counts, disks were homogenized in sterile Ringer's solution (1 disk/1 ml.); serial dilutions were carried out before estimation by a viable count method<sup>6</sup>.

Results are averages of at least three experiments; intermediate antibiotic concentrations are omitted for brevity.

the differences in water balance between plant associations. Thus it is worth trying to assess accurately the amounts of available water in the various tissues and the resistance to moisture transfer of each fraction to the main sap stream. If sufficient quantitative information could be collected, an electrical analogue method might be used to examine the course of diurnal and seasonal variations of the stored water under conditions of fluctuating absorption and transpiration. Clark and Gibbs<sup>4</sup> have published graphs for *Betula lutea* which seem to indicate that the change in bark moisture content lagged behind the sapwood by one month and the heartwood by three months.

There are certain implications of these considerations. First, when the water use of larger plants is measured by using the heat-flow technique to estimate sap flux in the stem, special care must be taken when calibrating the method by the transpiration from the crown<sup>5,6</sup>. While such a calibration is ideal in that it is non-destructive, the diurnal and other cyclical changes in water storage in the plant cause disparity between the flux of water from the leaves and that up the stem at any instant, and attempts must be made to take this into account. Secondly, some methods of investigating the water balance of large plants fail to take into account that over a given period the amount of internally stored water may have altered appreciably, only to be restored later by a change in the relative magnitudes of absorption and transpiration. Finally, it is possible that the internal moisture reservoir of larger plants may be a contributory cause of the greater water consumption they commonly exhibit compared with other forms of vegetation. Short grass turf, which has been used<sup>7</sup> to obtain an empirical factor to convert a meteorological estimate of evaporation from open water to that from vegetation well supplied with water, probably has minimal reserves of available internal water in the leaves, stem and roots. Other things being equal, it is possible therefore that the maximum rate of absorption of moisture by the roots would be higher than that for plants with considerable tissue storage which is available at a smaller suction than the soil moisture. Higher diffusion pressure deficits may thus be produced in the grass, giving rise to greater stomatal control, and smaller water use relative to larger plants.

### Reduction of Loss of Moisture by the Cuticle Wax Components of Grapes

THE grape cuticle serves as an effective barrier to the loss of water; but the cuticle layer or layers responsible for this property have not been identified. The chemical composition of the cuticular layers and their morphological structures, which are probably not independent, could both be important in determining the rate of cuticular transpiration, since there appears to be no correlation between the thickness of the cuticular walls and cuticular transpiration rate. This has recently been confirmed by Sitte and Rennier<sup>1</sup> for the transpiration of *Prunus*, *Agave* and *Sonchella*. This would imply that qualitative differences in the composition of cuticles are important in the regulation of water loss.

It was shown<sup>2</sup> that the grape cuticle wax is composed of a low melting 'soft wax' (80 per cent) consisting of long-chain alcohols, aldehydes, esters, free acids and

hydrocarbons, which is readily removed by petroleum ether, and a 'hard wax' consisting mainly of oleanolic acid which is removed by chloroform. Thus the possibility of removing one cuticular layer was of interest in the examination of cuticular transpiration of fruits, particularly so of grapes where the transpiration is not affected by the presence of stomates and their reactions.

Table 1. THE EFFECT OF REMOVING THE 'SOFT WAX' FRACTION FROM SULTANA GRAPES ON THE RELATIVE DRYING RATE\*

Time of exposure to petrol vapour (sec)	—	10	20	60	300
Amount of oleanolic acid removed (%)	0	1	2	5	12
Amount of soft wax removed (%)	0	26	53	63	85
Subsequent relative drying rate	1	1.5	2.0	2.5	4.4

\* The berries contained 136 µg/cm<sup>2</sup> cuticular wax of which about 80 µg were oleanolic acid. (Water loss of untreated control 1.7 mg H<sub>2</sub>O/h/g)

Ripe sultana berries of uniform size (1.5–2.0 g) exposed to the vapour of boiling petroleum ether for times varying from 10 to 300 sec lost increasing amounts of the soft wax fraction, whereas very little oleanolic acid was removed from the fruit under these conditions (Table 1). The rate of drying of untreated and extracted grapes was determined as follows: the berries were dried in wire trays in a ventilated cabinet at 50° and the relative drying rate was calculated from the loss in weight according to the formula:

$$\text{Relative drying rate} = [(W_0 - W_1)w_2]/[(w_0 - w_1)W_2]$$

where  $W_0$  and  $w_0$  = initial weights and  $W_1$  and  $w_1$  = final weights of untreated and treated samples respectively. It appears from the results presented in Table 1 that the drying rate depends on the amount of 'soft wax' fraction on the fruit and a total removal of all cuticular lipids with hot chloroform results in only a small increase of the drying rate (Table 2). Peeling of the fruit, that is, removal of the whole epidermal layer, yields only a comparatively small increase in the drying rate, indicating that the wax-free epidermis is no important water barrier. A similar observation has been made with the cuticles of apples<sup>3</sup>.

Table 2. RELATIVE DRYING RATE OF SULTANA BERRIES AT 50° C

Treatment	Without dipping	After immersion for 2 min in an emulsion of dipping oil	Increase in drying rate by dipping (%)
Control	1	2.5	156
Surface wax extracted with petrol vapour	4.6	5.3	14
Surface wax extracted with hot chloroform	5.7	7.6	20
Peeled	8.3	—	—

The increase of the cuticular transpiration of grapes by dipping solutions has been the object of several investigations. Cold dipping solutions are used in the production of light-coloured sultanas<sup>4</sup> and consist of an emulsion of a mixture of fatty acids, their ethyl esters and sulphonated compounds in alkaline solution. It has been established that very little or no wax is removed by the dipping procedure<sup>5,6</sup>, that the effect of dipping solutions on evaporation is reversible<sup>7</sup>, and that the electrical potential difference across the surface of grapes is not irreversibly changed<sup>8</sup>. Similarly the ultrastructure of the wax, visible under the electron microscope, is retained after removing the dipping solution by washing<sup>9</sup>. Chambers and Poëningham suggested that the surface of the wax plays an important part in the actions of dipping oils.

It was therefore of interest to compare the effect of removal of cuticular components by solvent extraction with that produced by dipping. The dipping oil was a commercial product and was used as an emulsion (2 per cent) in a solution of potassium carbonate (2.5 per cent). The drying rate is increased when the low melting 'soft wax' fraction is present in the grape cuticle (Table 2). Dipping solution has very little effect after removal of the 'soft wax' fraction with petrol or the total removal of cuticular wax with hot chloroform. The 'soft wax' fraction prevents water loss from the fruit probably acting simply as a hydrophobic layer that repels water both from within and without.

The lipids of dipping emulsions used to increase the drying rate of sultana grapes are absorbed and retained by the surface wax<sup>12</sup>. It is suggested that the addition of lipids (that is, fatty acids and their esters) with hydrophilic groups to the cuticular wax establishes a hydrophilic link between the hydrophobic surface of the grape and its watery contents, thus facilitating the flow of moisture through the cuticle.

### Mechanical Stimulation of Feeding in *Epiactis prolifera*

THE feeding mechanisms of coelenterates were the subject of much interest at the turn of the century, and were investigated by such notable biologists as Loeb<sup>1</sup>, Jennings<sup>2</sup> and Parker<sup>3</sup>. Renewed consideration has been given to these problems in the past few decades largely through the work of Pantin<sup>4</sup>, who used the sea anemone, *Anemonia sulcata*, and more recently through the experiments of Loomis<sup>5</sup>. The latter, who showed that small amounts of the tripeptide reduced glutathione activated feeding in the fresh-water *Hydra littoralis*, directed attention toward the chemical activation of feeding<sup>6,7</sup>. But the question of mechanical stimulation of feeding, although demonstrated in some sea anemones by earlier workers<sup>8,9</sup>, has been neglected in recent years. In this communication, I describe some observations which show that the feeding response of the sea anemone *Epiactis prolifera* can be repeatedly activated by remarkably slight mechanical stimulation with inert objects.

Specimens of *Epiactis prolifera* of approximately 1.2–2.5 cm diameter and 0.75–1.5 cm in height were collected from eelgrass beds in Friday Harbor, Washington. The animals were kept unfed in glass bowls on a sea-table of running fresh sea-water at about 13° C.

When a small piece of Whatman No. 1 filter paper (about 0.5 cm square) was placed gently on the tentacles, those tentacles touching the paper contracted toward the mouth, and the adjacent tentacles both to the right and left bent toward the paper. When the paper was placed forcefully on the tentacles, the 'wave of stimulation' was greater, more tentacles contracting. Usually within 30–60 sec after the tentacles first touched the paper, the lips of the mouth moved toward the paper and ingested it.

The tentacles are required for the reception of mechanical stimuli which activate feeding. The anemone did not seem to be aware of small pieces of paper placed on its oral disk only. If a nearby tentacle were made to touch the paper, however, within a few seconds adjacent tentacles started to envelop the paper and ingestion commenced.

This anemone can ingest a wide variety of inert and plant material. For example, a single specimen of *Epiactis* ingurgitated, in rapid succession during a 45-min span, Whatman filter paper, laboratory 'Kimwipes', paper towelling, pieces of eelgrass (*Zostera*) and the alga *Nucus*, small pebbles (0.2–0.3 g), and a piece of glass rod (0.2 g).

All these objects were regurgitated later, covered with a layer of mucus. The regurgitation time for inert objects varied, some objects being retained for 2–10 h.

Animal food offered to *Epiactis* was usually swallowed within a minute. The anemones were fed flesh from local clams, shrimps, limpets, and sabellid worms. They would not ingest specimens of *Epiactis* half their size, but would ingest specimens of their own species about one-tenth their size. The latter were regurgitated several hours later, unharmed.

Following ingestion of animal tissue, the response to mechanical stimuli became gradually sluggish. For example, 8 h after feeding on the clam *Protothaca* sp., the anemones took from 10 to 30 min to ingest bits of paper, while the fasting control devoured the paper within 30 sec. One day after this feeding, the anemones did not respond to the paper at all and the tentacles seemed to be insensitive to mechanical stimulation. When a fresh piece of flesh was placed on *Epiactis*, however, it was trapped by the tentacles and feeding commenced immediately. After two days, unused food was usually regurgitated, and within one day after regurgitation the anemones were again responding avidly to inert objects.

The rapid triggering of feeding by mechanical stimulation which was so striking in *Epiactis* was not observed among other sea anemones from the Friday Harbor area that were tested, including *Anthopleura elegantissima*, *Anthopleura xanthogrammica*, *Tealia* sp., *Metridium senile*, *Diadumene leucae*, and the zoanthid *Epizoanthus scotinus*.

This response of *Epiactis prolifera* is consistent and repeatable. Furthermore, the anemone is hardy and can be maintained in the laboratory with relative ease. Thus, it may afford a useful experimental system to study in coelenterates questions related to the nature, role and interaction of mechano- and chemo-receptors involved in co-ordinating a single response.

### Nitrogenous Excretion in Arachnids

ANIMALS are known to excrete ammonia, urea, or uric acid as end-products of protein metabolism. So far as we can ascertain, the problem of nitrogenous excretion in arachnids needs more investigation. Since the work of Gorup-Besanez and Will<sup>1</sup> in 1849, guanine was regarded as taking the place of uric acid as the main nitrogenous end-metabolite in arachnids. The method of synthesis of guanine in these animals is unknown<sup>2</sup>.

Vejropala<sup>3</sup> studied the excrements of the spider, *Epeira diademata*, by the specific enzymatic method of Schmidt<sup>4</sup> and found that guanine accounts for up to 12 per cent of the dry weight of the excrements. Schmidt *et al.*<sup>5</sup> found that guanine accounts for more than 85 per cent of the total nitrogen of the excrements of two species of spiders, the silk spider, *Nephila claviceps*, and the garden spider,

*Argiope aurantia*. Hypoxanthine, xanthine and uric acid were present in not more than negligible amounts. Atkinson and Chorlton<sup>8</sup> found that 40 per cent of the excretory material of the huntsman spider, *Delena cancerides*, was guanine, forming 71 per cent of the total nitrogen excreted and no other purines were present.

Guanine was also found to form the main nitrogenous end-metabolite in the excreta of scorpions. Gregoire *et al.*<sup>7</sup> stated that guanine represented about 90 per cent of the nitrogen excreted in two species of scorpions, *Androctonus australis* and *A. amurensis*. Adenine and hypoxanthine were absent, whereas small amounts of amino-acids and agmatine were present. In another scorpion, *Palamnaeus bengalensis*, Koch *et al.*<sup>9</sup> detected the presence of adenine, hypoxanthine and uric acid in the excreta. As such, animals excrete several intermediates of the same excretory cycle, they considered them to be physiologically less efficient than those excreting a single intermediate. Said<sup>6</sup> found that the excreta of the scorpion, *Buthus quinquestratus*, was mainly formed of guanine as it formed 86.27 per cent of the total nitrogen excreted; xanthine and urea were absent whereas ammonia and uric acid formed 8 and 0.19 per cent of the total excretory nitrogen respectively. Rao<sup>10</sup> and Rao and Gopalakrishnareddy<sup>11</sup>, working on the excreta of some scorpions and certain other arachnids, found that nitrogen is excreted predominantly as guanine. Uric acid accounted for 8–12 per cent of the total excretory nitrogen and was also detected in the poison and coxal glands of the scorpions, *Heterometrus* and *Buthus*.

The work recorded here was undertaken on the excrements of spiders and scorpions in Egypt, in an attempt to add more knowledge to the problem of excretion in arachnids. Excreta from 15 specimens of the scorpion, *Buthus quinquestratus* H.E., were collected in 10 days during September. Excrements from 7 specimens of the spider, *Lycosa urbana*, were collected during 25 days of August and September. The excreta of both animals were white deposits spotted with black or dark faeces.

Excreta were left to dry in a desiccator until weight was constant and then ground in a small mortar. Methods of analysis of excreta for total nitrogen, ammonia, urea and uric acid are similar to those used by one of us<sup>12</sup> for the analysis of urinary concretions of reptiles. Total nitrogen was estimated on the whole excreta; a weighed portion was dissolved in warm water and the soluble portion was used for the determination of ammonia, urea and uric acid. The water-insoluble part was dissolved in 1 per cent lithium hydroxide solution and the soluble portion was used for the determination of uric acid, as lithium hydroxide is a good solvent for uric acid and normally insoluble urates. Another weighed part of the deposit was dissolved in ammonia-water (1:1) to dissolve guanine, which is readily soluble in this solution. Guanine was measured in this solution by the method described by Williams<sup>13</sup> for the determination of guanine in urine.

Constituents / 1 g deposit	Scorpion ( <i>Buthus</i> )		Spider ( <i>Lycosa</i> )	
	As N	As % of total nitrogen	As N	As % of total nitrogen
Total nitrogen	243.000	100	177.419	100
Water soluble constituents				
Ammonia nitrogen	0	0	0	0
Urea nitrogen	0	0	0	0
Uric acid nitrogen	7.496	3.085	0.266	0.150
Water insoluble constituents				
Uric acid nitrogen	0.183	0.065	0.200	0.113
Ammonia water soluble constituents				
Guanine nitrogen	135.200	55.663	167.410	94.390

The results are shown in Table 1. The total nitrogen of *Buthus* and *Lycosa* was 243 and 177.419 mg/g deposit respectively. Ammonia and urea were completely absent from the deposits of both animals. Uric acid nitrogen formed about 3 per cent of the total nitrogen excreted in scorpions, while it was present in very small traces in the excreta of spiders. Such analysis indicates that these arachnids are not grouped under the three main divisions,

ammonoteles, ureoteles, or uricoteles, which excrete respectively ammonia, urea or uric acid as the main nitrogenous end-product of protein metabolism. Scorpions and spiders form a separate group which excrete guanine as the main nitrogenous end-metabolite of protein metabolism. The guanine excreted forms about 55 and 94 per cent of the total excretory nitrogen in the scorpion and spider investigated respectively.

## MICROBIOLOGY

### Effect of Actinomycin D on the Infectivity of *Trypanosoma cruzi*

PARTIAL immunity against a virulent and lethal strain of *T. cruzi* has been obtained in mice by several procedures<sup>1-4</sup>. All these procedures lead to a limited protection and are characterized by the appearance of parasites in the blood. The use of killed flagellates induces little or no resistance against the virulent strain<sup>1,4</sup>, suggesting that a mild host infection is an indispensable prerequisite for the development of even partial immunity.

During studies of protein and nucleic acid synthesis in *T. cruzi*, it was found that actinomycin D was a potent inhibitor of the growth of the organism *in vitro*. Furthermore, the inhibition of growth remains after the flagellates are washed and resuspended in a medium free of actinomycin D. The earliest detectable effect of the drug was a potent inhibition of ribonucleic acid synthesis, followed by inhibition of protein and deoxyribonucleic acid synthesis. Moreover, the organisms maintained in the presence of actinomycin D, although manifesting normal motility, appeared to lose their potentiality to multiply as indicated by their inability to incorporate radioactive thymidine into DNA. These organisms, however, retained the ability to protect animals against infection by a virulent strain of *T. cruzi*.

The flagellates were cultivated at 28° C either in a medium containing liver infusion, tryptose (LIT medium), salts, serum and haemoglobin or a medium in which the liver infusion and tryptose were replaced by lactalbumin hydrolysate (Lacto medium). The composition of the former medium was made available to us by Dr. Robert G. Yeager, of Tulane Medical School, New Orleans. Intraperitoneal injections of a suspension of flagellates from culture or 200,000 blood forms of the flagellates, collected from mice heavily infected by a virulent strain, were used to inoculate mice.

Microscopic examination of the blood of infected animals and xenodiagnosis were both used to detect parasites in blood. The latter, a highly sensitive procedure in mice, was employed as a check on the microscopic examination to ensure that the blood of animals which had received injections of actinomycin D-treated flagellates did not

harbour the parasite. In this procedure, five *Triatoma infestans*, one of the vectors of *T. cruzi*, were used to feed on each mouse. The mice were bled to death by the bugs. Examinations of the triatomids were carried out two months after the blood meal. Microscopic examination of all mouse blood was carried out before, and 9-15 days after, the inoculation of the virulent flagellates.

The results of the multiplication potentiality of *T. cruzi* measured as a function of the rate of incorporation of tritiated thymidine into DNA are shown in Table 1. It is clear that the actinomycin D-treated organisms lost their ability to incorporate tritiated thymidine into DNA. Other inhibitors, for example mitomycin C and 5-fluorouracil-2'-deoxyriboseide, also inhibited the growth of the organisms *in vitro*, but were not as effective in inhibiting the incorporation of radioactive thymidine under these conditions.

Table 1. RATE OF INCORPORATION OF TRITIATED THYMIDINE INTO DNA OF ACTINOMYCIN D-TREATED *Trypanosoma cruzi*

Pretreatment of flagellates	24 h	48 h	72 h
None	100,100	120,000	165,000
Actinomycin D	0	0	0

Flagellates, cultivated for 3 days in Lacto medium containing 1 µg/ml. of actinomycin D, were centrifuged and resuspended in 3 ml. of LIT medium containing 1 µc. of tritiated thymidine/ml. The final suspension contained approximately  $1.5 \times 10^7$  flagellates/ml. This, together with identical suspensions of flagellates in which actinomycin D was omitted, was incubated at 25° C. At the indicated times, the suspensions were centrifuged and the sediments washed twice with 0.4 M perchloric acid and followed by two washings with 80 per cent ethanol. The final sediments were resuspended in 0.1 N NaOH. The radioactivity was measured in a Packard "Tri-carb" liquid scintillation spectrometer.

Suspensions of the actinomycin D-treated organisms were injected into 20 mice ( $3 \times 10^6$  organisms per mouse) and followed by a similar injection one week later. Two weeks after the last injection, eighteen of the twenty mice and twenty control mice were injected with blood of animals heavily infected with the virulent strain. Each mouse received approximately  $2 \times 10^4$  organisms. The results of this experiment are shown in Table 2. It may be seen that a previous exposure to actinomycin D-treated flagellates resulted in virtually a complete protection against a subsequent exposure to the virulent organisms. The control or untreated mice, on the other hand, all showed very high blood levels of the parasite and died within 13 days of exposure to the virulent flagellates. Particularly significant and perhaps even more important than the high degree of protection offered by the actinomycin D-treated flagellates is the observation that the protection was achieved without the appearance of blood parasites due to the injection of the metabolically inhibited organisms. It should be mentioned that other experiments carried out with groups of twenty mice (without the xenodiagnosis control) showed similar results.

Table 2. PROTECTIVE EFFECT OF *Trypanosoma cruzi* PREINCUBATED WITH ACTINOMYCIN D AGAINST INFECTION BY A VIRULENT STRAIN

Treatment	No. of mice	Blood parasite level		Survival time (days after injecting the virulent flagellates)	No. of survivors
		Before virulent strain	After virulent strain		
Control	20	—	1,000 to 4,230	12 ± 1	0
Actinomycin D	18 2†	0 0	1 to 4 —	* —	18 —

\* All animals in good health were killed after 90 days.

† Animals used for xenodiagnosis tests.

Twenty mice were inoculated with  $3 \times 10^6$  flagellates cultivated for 3 days in Lacto medium containing 1 µg per ml. of actinomycin D. The inoculation was repeated one week after the first injection. Two weeks after the second inoculation 18 of the mice and 20 untreated mice were inoculated with  $3 \times 10^4$  virulent flagellates.

Blood parasite levels are expressed as the number of parasites in 200 microscopic fields ( $\times 230$ ), except when no parasites were found, in which case 4,000 microscopic fields were examined.

The two mice from the actinomycin group that did not receive the virulent strain were used for xenodiagnosis two weeks after the second inoculation, to determine whether a mild infection (very difficult to detect by direct

blood examination) could be detected by this sensitive method. No parasites were found in either the faeces or the intestine of the *Triatoma* bugs, even two months after the blood meal.

Thus it appears that actinomycin D-treated flagellates, though devoid of infective capacity, retain a high degree of antigenic competence. The recent results of Johnson, Neal and Gall<sup>6</sup>, which demonstrate that adjuvants increase the protective effect of *T. cruzi* antigens, suggest a means of improving that of actinomycin D-treated flagellates.

## VIROLOGY

### Genetic and Non-genetic Factors in Chromatographic Behaviour of Poliovirus

SOME variants of poliovirus ( $E^+$ ) do not adsorb on DEAE-cellulose provided neutral 0.01–0.02 M phosphate buffer is used as a diluent; under identical conditions some other variants ( $E^-$ ) are almost completely detained on the ion-exchanger and can be eluted only with solutions of increased ionic strength<sup>1,2</sup>. The  $E$  character of poliovirus may be considered as a genetic property which has no complete correlation with any other marker investigated so far<sup>3-5</sup>.

In this report we furnish evidence that in some cases the expression of  $E$  phenotype is critically dependent on the virus growth conditions, and particularly on the presence of cystine.

Methods of chromatography and of virus titration were described in detail earlier<sup>1,4</sup>. Briefly, they were as follows: virus, adsorbed on DEAE-cellulose column, was first eluted by 40 ml. of 0.02 M phosphate buffer, pH 7.1, and then by 40 ml. 0.85 per cent NaCl in the same buffer. The virus content of each fraction (10 ml.) was assayed by plaque method. As representatives of  $E^+$  and  $E^-$  variants of poliovirus, the lines M-I-2p and M-III-2p were used, respectively; these lines are plaque-purified derivatives of the Mahoney strain<sup>4</sup>. Viruses were grown in cultures of kidney tissue of *Macacus rhesus* in the medium containing 0.5 per cent lactalbumin hydrolysate in Earle's salt solution. Table 1 shows that the chromatographic behaviour of these variants does not change significantly either after one passage in the cystine-free Eagle's medium or after treatment with cystine *in vitro* by the method of Pohjanpelto (12 h at 37° C in 0.01 per cent cystine in borate buffer, pH 9) (ref. 7). It may be noted that this treatment results in a considerable increase of thermostability of both populations (M-I-2p and M-III-2p).

Quite different results were obtained, however, with another variant derived from M-III-2p by four consecutive passages in the cystine-free Eagle's medium. This procedure resulted in the formation of a population (M-III<sub>4</sub>) which differed from the original M-III-2p, being predominantly an  $E^+$  population. After one passage in the lactalbumin hydrolysate medium, the elution pattern

Table 1. CHROMATOGRAPHIC BEHAVIOUR OF POLIOVIRUS POPULATIONS UNDER DIFFERENT CONDITIONS

Variant	Virus yield (per cent of infectivity loaded on to column)			
	(a) 'Buffer fraction'	(b) 'Salt fraction'	(c) 'Buffer fraction'	(d) 'Salt fraction'
M-I-2p	76	2	82	77
M-III-2p	<1	99	92	<1
M-III <sub>4</sub>	78	8	65	<1

(a) Virus grown on cystine-free Eagle's medium; (b) virus grown on the lactalbumin hydrolysate medium; (c) virus grown on cystine-free Eagle's medium, and treated with cystine *in vitro*. 'Buffer fraction'—the fraction of virus infectivity which is eluted by 0.02 M phosphate buffer, pH 7.1. 'Salt fraction'—the fraction of virus infectivity which is eluted by 0.85 per cent NaCl in 0.02 M phosphate buffer, pH 7.1.

of M-III<sub>4</sub> was changed for E<sup>-</sup>; the modified population again regained its E<sup>+</sup> phenotype after one passage in the cystine-free Eagle's medium (Table 1). We supposed that the change of chromatographic behaviour was due to the presence of cystine in the lactalbumin hydrolysate medium. This assumption was confirmed by experiments with the treatment of M-III<sub>4</sub> with cystine *in vitro*. Such treatment also results in change-over of E<sup>+</sup> phenotype for E<sup>-</sup> (Table 1).

Thus, the chromatographic behaviour of M-III<sub>4</sub> (its E character) is not, strictly speaking, a genetic marker. But the capacity of this variant to react with cystine in a manner that leads to changes in elution properties of the population may be considered as a special genetic character. Such cystine-response variants may be designated E<sup>r</sup>.

We would like to point out that treatment of M-III<sub>4</sub> with some other sulphur-containing compounds (thioglycolate, mercaptoethanol) also results in analogous change of chromatographic behaviour (E<sup>+</sup> → E<sup>-</sup>).

### Protective Effect of Neonatal Thymectomy on Cystic Disease Induced in Rats by Rous Sarcoma Virus

L. Zilber and I. Kryukova<sup>1</sup> have described a peculiar cystic-haemorrhagic disease caused by Rous sarcoma virus (RSV) in rats infected when newly born. G. Svet-Moldavsky and A. Skorikova<sup>2</sup> have obtained analogous results later on confirmed by other investigators. The morphological investigation revealed that this disease is connected with disease of lympho-reticular tissue of lymph nodes, spleen, lungs and endothelium of small lymphatic vessels<sup>3</sup>. Cysts are formed due to the whole complex of proliferative and destructive processes which change mainly the reticular (reticulo-endothelial) cells and block the lymph-stream.

Various strains of RSV differ in their capacity to cause cystic disease in rats. There is a direct relation of frequency, rate of development and severity of disease on the infecting dose of virus. The neutralization of virus with a specific anti-serum prevents the disease<sup>4</sup>.

Simultaneously the morphological data indicate that the dynamics of cyst formation is connected with cellular reactions and vascular diseases characteristic of a delayed-type sensitivity.

Taking into account the data concerning the important role of thymus in immune reactions of the organism<sup>5</sup>, we

have investigated the influence of neonatal thymectomy on the development of cystic lymphadenopathy induced in rats by RSV.

We used the Carr-Zilber strain of RSV which shows practically 100 per cent cystogenic activity. A 30 per cent extract of chicken sarcoma tissue in saline centrifuged for 20 min at 2,500g was used as the source of virus. The infectious titre of virus was 1:10,000 in 0.1 ml. Rats of the Wistar strain, less than 24 h old, were thymectomized using the technique of Jankovic *et al.*<sup>6</sup>. 1-2 h later the rats were infected subcutaneously (into the interscapular region) with 0.2 ml. of virus.

The inoculations, of 0.5 ml. in dose, were repeated on the second and fourth days of life.

Table 1. FREQUENCY AND RATE OF DEVELOPMENT OF CYSTIC DISEASE INDUCED BY RSV IN RATS THYMECTOMIZED AT BIRTH

Complete thymectomy	Age of rats in weeks when killed	No. of rats killed by this time
0/17*	2	3
	3	3
	4	1
	8	2
	9	3
	11	2
	15	2
	17	1
Partial thymectomy	Weeks after inoculation of RSV, cysts first seen	No. of rats with cysts by this time
(a) Small or microscopic remnants of thymus 9/16	5	1
	7	2
	8	3
	9	1
	13	2
(b) Large remnants of thymus 14/14	2	0
	3	5
Non-thymectomized rats/control 15/16	2	15

\* Numerator—No. of rats affected; denominator—No. of rats infected with RSV.

The results, summarized in Table 1, show:

(1) In non-thymectomized rats (control), the cystic diseases identical to those described before appeared 2 weeks after the inoculation. (2) In rats subjected to complete thymectomy, cysts appeared in none of the cases. (3) When the rats were partially thymectomized the results were quite different depending on the size of the remaining part of the thymus: when the remaining part was large we noticed a certain acceleration of the disease development along with impetuous regeneration of thymus. When the remnants of thymic tissue were small or microscopic, cysts appeared in 9 out of 16 rats and the process of their formation was retarded.

Thus, the results of experiments demonstrate that the neonatal thymectomy suppresses, or at least delays, the development of cystic disease caused by RSV in rats. Since neither the cellular elements of the thymus itself nor the small lymphocytes are the object of the direct pathogenic virus action<sup>7</sup>, we can assume that the immune mechanisms controlled by the thymus play a very important part in the genesis of the cystic syndrome. We propose as a hypothesis the following scheme of cystic disease pathogenesis:

(1) Infection of new-born rats with chicken sarcoma extract causes the alteration of antigenic capacities of lympho-reticular tissue cells affected by RSV (together with enhancement of cell proliferation and possibly also with direct necrotizing virus action).

(2) The further development of the disease is connected mainly with the auto-immune response directed against the cellular elements 'heterogenized' by the virus. This reaction is analogous to the homograft immune response and presumably involves a delayed hypersensitivity mechanism. The serological and morphological data suggest that humoral factors of immunity do not play an essential part in the reaction of rats infected with RSV.

Thus the cystic disease is considered to be due to a virus—autoimmune disease of a rather peculiar type. The whole complex of proliferative and destructive changes due to which the cysts appear can be estimated as a result of

direct pathogenic action of the RSV on the infected cells and immunomorphological phenomena. Neonatal thymectomy brings about a considerable suppression of delayed hypersensitivity reaction<sup>6</sup> and thus excludes one of the links (probably the main one) of the cyst formation process. Apparently an analogous phenomenon occurs in the course of lymphocytic choriomeningitis in mice and neonatal thymectomy has a protective effect<sup>7,8</sup>.

Recently we have obtained similar results concerning the suppressive effect of neonatal thymectomy on the cystic disease in mice (described by us earlier<sup>9</sup>) injected with the mixture of sheep lung adenomatosis tissue extract and polyoma virus; simultaneously under these conditions we have noticed the aggravation of the oncogenic action of polyoma virus.

## GENETICS

### Polymorphism in the Red Protein Isolated from Milk of Individual Cows

GENETICALLY determined polymorphism of human and other primate transferrins, the iron-binding proteins in blood, has been established by starch-gel electrophoresis<sup>1,2</sup>. The transferrin in cattle differs from that in humans since cattle homozygous for an allele have been shown to contain more than one transferrin<sup>3,4</sup>. The red protein, also called lactotransferrin, is an iron-binding protein found in cow's milk and has now been found to be polymorphous by gel electrophoresis. Although serum transferrin resembles the red protein in size, absorption spectra, and amount of iron bound per mole of protein, it differs in electrophoretic mobility and amino-acid content<sup>5,6</sup>.

Red protein isolated from the milk of individual cows in the experimental herds at Beltsville, Maryland, was examined by zone electrophoresis. Since the red protein is a minor protein in milk, it must be isolated before electrophoretic typing can be carried out. Also, it should be reasonably pure, since a number of other minor proteins with similar mobilities are found associated with the red protein fraction.

Zone electrophoresis by the Raymond method<sup>7</sup> at pH 9.0 has recently been applied to milk proteins<sup>8</sup> and was found to give good resolution of the red protein when used at 5 per cent gel concentration. For most comparisons shown here the red protein was isolated from the casein fraction<sup>9</sup> or the whey fraction of milk<sup>9</sup>. Good agreement in electrophoretic patterns was found for proteins prepared by either method.

Variation in gel-electrophoretic patterns at alkaline pH of the isolated red protein is shown in Fig. 1, numbers 1 through to 5. The photographic reproduction does not show some of the minor bands as clearly as they could be seen in the original gel. The bands are marked according to their mobility—A for the fastest and D for the slowest. Band D generally stains heavily, with each succeeding zone becoming lighter; however, with number 3 the D band is faint. Number 5 is typed (C), D, the parenthesis indicating little protein in the C zone. Numbers 1, 2, and 4 are typed B, C, D, while 3 is A, B, C, (D). The protein in 1 and 2 was isolated from the whey and casein fractions of milk from a single cow. A tabulation of the types according to breed is shown in Table 1.

Table 1. A COMPARISON OF THE ELECTROPHORETIC TYPE OF RED PROTEIN WITH BREED

Breed	Total	Electrophoretic zone*			
Ayrshire	2†, ‡		(C)	D	
Ayrshire	1†	B	C	D	
Brown Swiss	2†		(C)	D	
Brown Swiss	2(2†, 1†)	B	C	D	
Guernsey	3(1†, 2†)	B	C	D	
Holstein	1†, ‡	(A)	B	C	D
Jersey	1†	(A)	B	C	D
Jersey	1†			C	D
Jersey-Brahman	1‡	B	C	D	
Holstein-(mixed breed)	1‡, †	A	B	C	(D)
	16				

\* Letters in parenthesis indicate a very small amount of protein.

† Red protein prepared from casein fraction.

‡ Red protein prepared from whey fraction.

§ Red protein prepared from  $\beta$ -lactoglobulin fraction.

|| Red protein prepared from colostrum milk of this cow.

As some of the bands might result from the binding of varying amounts of iron, electrophoretic determinations were made on protein solutions to which excess iron ions

Fig. 1. Gel-electrophoretic patterns of the red protein. Vertical gel, 9.0: 1-5, protein from individual cows; 6, apoprotein; 7, control. Disk gel, pH 4.3. 8, protein from individual cow.

were added. The resulting electrophoretic patterns were unchanged. In another experiment the iron was dissociated from the red protein by adjusting a protein solution to pH 2.0 and removing the iron with a 'Dowex 50' resin in the chloride form. An electrophoretic comparison (Fig. 1, numbers 6 and 7) shows that the zones for the apoprotein, although less sharp, have a greater mobility and are out of phase with those of the control. The consistency of the mobilities of the various red protein types and the fact that the addition of iron does not change the electrophoretic patterns suggest that a small variation in iron will not significantly alter the patterns.

Polymorphism in the red protein has also been found at acid pH, as shown in Fig. 1, number 8. Disc electrophoretic determinations were made in 7.5 per cent gel concentration, pH 4.3, according to Reisfeld *et al.*<sup>10</sup>. A current of 60 m.amp (12 tubes) was applied long enough for the protein to move through about 70 per cent of the lower gel. In contrast to the variation found at alkaline pH, all the proteins examined show a major fraction of 3 closely-related bands.

Electrophoretic differences at alkaline pH in the red protein isolated from milk of individual cows suggest the existence of a genetically controlled polymorphism. Final proof will require a study of larger numbers of individual animals than is practical with the present isolation procedures.

Preliminary peptide maps indicate differences in a few peptides, and this will be the subject of future work.

### Method for demonstrating the Chromosomes in Adult Human Spleen Cells

To obtain chromosome preparations from *in vitro* cultures of human peripheral blood is now a routine laboratory procedure. Baker and Atkins<sup>1</sup> and Bain and Gauld<sup>2</sup> have extended this technique to human foetal and infant spleen and adult lymph nodes. The present communication describes the further extension of this method, to demonstrate the chromosomes of adult human spleen cells following culture *in vitro*.

In all, five spleens and one spleniculus have been studied as shown in Table 1. Each was freshly obtained from a patient undergoing splenectomy for therapeutic reasons.

Approximately 0.5 g of splenic tissue was taken aseptically and placed in a Petri dish, moistened with 'Medium 199' (Glaxo Laboratories, Ltd., Greenford, Middlesex). The capsule was removed, and the remaining tissue was cut into small fragments with scissors, and then further reduced to a cell suspension in 'Medium 199', using a glass piston blender, after the method of Woodruff<sup>3</sup>. This suspension was washed by centrifuging at 580g for 5 min, and resuspended to a total volume of 10 ml. in fresh 'Medium 199'.

The washed cell suspension was transferred to a siliconized, heparinized 'Universal' container and 0.4 ml. of phytohaemagglutinin (Burroughs, Wellcome and Co., London) was added, the whole being placed in a refrigerator at 4° C for 80 min. At the end of this period the erythrocytes present were seen to have sedimented, and the process was further accentuated by centrifugation at 180g for 3 min. The supernatant was then removed and a nucleated cell count was performed on it. From this cell suspension aliquots of 6-8 ml. were prepared for incubation in further 'Universal' containers as follows.

The cell suspension was diluted with further 'Medium 199', and human group AB Rh +ve serum was added to a concentration of 20-25 per cent, so that the final cell concentration, after addition of the serum, was between 1 and 1.5 million cells per ml.

The culture was incubated at 37° C for 4 days. Any alkalinity in the culture was corrected with a jet of 5 per cent CO<sub>2</sub> in 95 per cent O<sub>2</sub>, initially, and thereafter at 12-hourly intervals.

On the fourth day, 0.1 ml. of a 0.02 per cent (w/v) solution of 'Colcemid Pure Substance' (Ciba Laboratories, Ltd., Horsham, Sussex) was added to each ml. of the culture and incubation was continued for a further 3 h.

The further processing of the material closely followed the method used for cultures of peripheral blood and will therefore be only briefly summarized.

The cells collected from the culture were treated with hypotonic (0.95 w/v per cent) sodium citrate at 37° C and then fixed in a mixture of 3 parts ethyl alcohol to 1 part of glacial acetic acid.

Immediately before making the slides the fixative was changed to one of 3 parts methyl alcohol to 1 part glacial acetic acid, the cells being suspended in one drop of this solution, so that it possessed a 'milky' opalescence.

Slides were cleaned with absolute alcohol, dried, and then cooled by placing on a block of carbon dioxide snow after the method of Fox and Zeiss<sup>4</sup>. The cells were dropped on to the cooled slide, using a Pasteur pipette, and the slide was then rapidly heated in the flame of a spirit lamp. Finally, the slides were stained with 1 per cent aceto-orcein and mounted in 'D.P.X.'.

Table 1. CLINICAL DETAILS OF THE FIVE PATIENTS STUDIED

Patient	Age and sex	Spleen size	Disease and operation
1	Male, 54	Normal	Carcinoma of head of pancreas Splenectomy and removal of tail of pancreas with intestinal anastomosis
2	Male, 20	Normal	Rupture of spleen Splenectomy
3	Female, 50	Increased	Carcinoma of stomach Oesophago-gastroectomy
4	Female, 2	Increased	Spleroerythosis Splenectomy
5	Male, 54	Increased	Carcinoma of stomach Oesophago-gastroectomy

The method described was found to yield a good collection of well-spread mitotic figures in replicate cultures of the spleens from Cases 3, 4 and 5 where the spleen showed evidence of hyperplasia. It was observed, however, that cell division was most rapid in those cultures which showed a frequent change to an alkaline pH.

Only scanty mitotic figures were obtained from the cultures of spleens from patients 1 and 2 and from the spleniculus in Case 5. In these cases there was no splenic hyperplasia.

A similar method applied to the normal rat and mouse spleen, using rat serum, previously heated to 56° C for 1 h, to enrich the culture medium, was found unsuitable for the demonstration of chromosomes (Symes, unpublished observation).

These findings, together with those cited here<sup>1,2</sup> wherein chromosomes were only demonstrated in the foetal and infant spleen, suggest that prior splenic hyperplasia may be important for success. Nevertheless, the method would seem to be of value as a means of assessing the viability of spleen cell suspensions used as haemopoietic

replacement following chemotherapy<sup>1</sup>, and *per se* in the treatment of malignant disease<sup>2</sup>.

We thank Dr. G. H. Tovey for generous supplies of human serum, and Mr. J. Wegrzyn for his assistance.

## AGRICULTURE

### Significance of Differences between Variety Yields under Experimental and Farm Conditions

PREVIOUS work has shown that if farm yields are plotted against experimental yields they lie along a curve which has a slope of 45 degrees at low values and is almost horizontal at high values<sup>1</sup>. This occurs because, in years favourable to the crop, farm yields do not increase by the same proportion as experimental yields.

This result suggests that it may be erroneous to assume that significant differences between yields of plants obtained under experimental conditions will also be significant on farms. This becomes obvious when the differences between two points on the curve are measured on the abscissae and the ordinate of Fig. 1. In unfavourable years the difference between the yield of two crop varieties in an experiment is  $A_1B_1$ . On farms it would be the smaller but still substantial differences  $A_1B_1$ . Although a much larger difference in the yield of the two varieties  $A_1B_1$  may be obtained in favourable years in an experiment, the difference in yield on farms  $A_1B_1$  will actually be smaller than in unfavourable years. If farm yields fail to reflect the large differences between the yields obtained under experimental conditions in favourable years, it is possible that significant differences due to varieties, fertilizers, insecticides and other cultural practices obtained on an experimental scale would not be significant on a farm scale.

It is possible to examine the differences in the yields of varieties of sugar cane in experimental plots and on farms. In Queensland (Australia) the Bureau of Sugar Experimental Stations has carried out variety trials of commercial strains of sugar cane in all major sugar areas using the latin square or randomized block techniques over a period of years. Differences in the yields of varieties are not published unless they are significant at the 5 per cent level. The cultural and manual practices used in the experiment are similar to those used on farms in the mill

Fig. 1. Differences between yields on farms and in experiments in favourable and unfavourable years

Table 1. COMPARISON OF HIGH- AND LOW-YIELDING VARIETIES OF SUGAR CANE IN EXPERIMENTAL TRIALS AND ON FARMS

Variety pair	Yields (tons cane per acre)				Total area of farm crops in mill area (acres)	
	Experimental plots High-yielding variety	Experimental plots Low-yielding variety	District average High-yielding variety	District average Low-yielding variety	High-yielding variety	Low-yielding variety
A	22.26	20.97	17.6	15.7	6698	1011

K	33.28	26.28	16.6	24.4	1607	808
L	41.87	39.06	20.6	32.5	1400	4122
Mean	36.11	28.35	23.8	24.3	3328	2538
Mean difference	+7.8		-0.5			

area in which the trial is conducted; the concurrent yields of individual varieties of sugar cane produced on farms are collected for each mill area by the Bureau of Sugar Experimental Stations (N. J. King, personal communication).

Using this information, a comparison can be made between any two varieties of different yield in a particular trial in a particular year. Similarly the average yields of the same high-yielding variety can be compared with the average yield of the same lower-yielding variety in the mill area in which the trial is located. Unfortunately mill areas are restricted to a few varieties and, if areas where trials and farm crops are partially or fully irrigated are excluded, only twelve pairs of varieties can be compared with farm data. This comparison is made in Table 1.

In the experiments the mean yield of the high-yielding varieties was 7.8 tons (27 per cent) higher than that of the lower-yielding varieties and this difference was significant at the 1 per cent level. On farms there was no significant difference between the yield of the high- and low-yielding varieties. The lack of difference on farms between high- and low-yielding varieties cannot be explained by the total acreages of each variety grown on farms. Substantial acreages of all the varieties studied were produced, and there was no correlation between acreage of crop grown in the mill area and difference between the yield of high- and low-yielding varieties on the farms.

This investigation was restricted to a comparison between experimental yields and average farm yields of high- and lower-yielding varieties of sugar cane, but it does suggest that, although a variety may give significantly higher yields than other varieties under experimental conditions, this difference may not exist on farms even when climate, soil and cultural practices are similar to those in the experiment. It is possible that this failure of farm yields to reflect experimental trends may also be true of comparisons between different levels of fertilizer or different cultural practices. Further comparisons between differences in yields in experiments and on farms would be necessary to establish the magnitude and significance of differences which exist on farms for a given difference established in an experimental trial at a particular level of significance. For the data presented here a difference in the average yield of 27 per cent, which is significant at the 1 per cent level in experiments, is not reflected in average farm yields. It is possible that the reduction in the difference in yield, which occurs when a practice is translated from experiment to farm, changes with the variable or the type of crop being examined, and that the actual degree of reduction in yield for particular variables and different crops must be found before the results of experiments can be applied to farming.

## SOIL SCIENCE

## Role of Exchangeable Potassium and Magnesium on Caesium Absorption on Marine Sediments

The potassium ion fixed into the interlayer spacing of a clay mineral is not easily replaced, and the results of chemical analysis cannot distinguish these interlayer potassium and the structural potassium. Therefore, the total potassium obtained in the chemical analysis includes the gross structural potassium and the edge-site exchangeable potassium. One may assume, therefore, for the comparison of the adsorbability of various clay minerals, that the smaller the ratio of structural potassium, or alternatively the larger the ratio of exchangeable potassium to the total potassium, the greater will be the adsorption of metal ions, especially of rubidium and caesium, which are adsorbed in the dehydrated states having rather small cationic radii and can easily penetrate into the interlayer opening.

This assumption was exemplified in our investigation of the adsorption of caesium on Pacific pelagic and terrigenous sediments, containing illite, chlorite, and montmorillonite, the details of which will be published elsewhere. Samples were fractionated into three portions according to the size of particles. The plot of the distribution coefficients versus the ratio of exchangeable potassium to the total potassium ( $R_K$ ) resulted in straight lines intercepting at the origin; the slopes of them differ from one sample to another. Such relation was also found for the ratio of exchangeable magnesium to the total magnesium ( $R_{Mg}$ ), but not for the respective ratios of sodium and calcium.

For the purpose of assigning to which clay mineral is worked either one of the ratios,  $R_K$  and  $R_{Mg}$ , cristobalite, kaolinitic montmorillonite, illitic chlorite, and two illitic kaolinites were fractionated into two or three portions according to the particle sizes ranging from 1 to 44 $\mu$ . The distribution coefficients of caesium-134 were determined in triplicate in water and in N sodium chloride solution, both at pH 8.0. It was found that linear relation held only for kaolinitic montmorillonite when  $K_d$  versus  $R_K$  plots were made (Fig. 1), while  $K_d$  versus  $R_{Mg}$  plots resulted in straight lines, intercepting at the origin, only for illitic chlorite (Fig. 2). From the clay mineralogical data of the samples used, the role of  $R_K$  can be attributed to montmorillonite, whereas that of  $R_{Mg}$  can be attributed to

Fig. 1. Linear relation between  $K_d$  and  $R_K$  for the adsorption of caesium on kaolinitic montmorillonite

Fig. 2. Linear relation between  $K_d$  and  $R_{Mg}$  for the adsorption of caesium on illitic chlorite

chlorite. These results are consistent with previous reports<sup>1</sup> showing that potassium fixation occurs in montmorillonite and magnesium fixation occurs in degraded chlorite.

In the case of marine sediments, the straight lines obtained in the plot of  $K_d$  versus  $R_K$  and  $K_d$  versus  $R_{Mg}$  exclusively intercept at the origin, while in the present cases  $K_d$  versus  $R_K$  plots do not pass the origin. This situation can be understood because the marine sediments are completely saturated by the metal ions composing sea-water, so that the unbalanced charges in the structural units due to the lattice substitution are completely balanced by these ions. On the other hand, in the present montmorillonite, charges given by the lattice substitutions are available for the adsorption of caesium and the definite magnitude of adsorption even at  $R_K = 0$  will result. In the presence of N sodium chloride solution, the plot still does not intercept at the origin, though the distribution coefficients markedly decreased as compared with those in water, presumably due to the incomplete balancing of the charges emerging from the lattice substitution by sodium ions of this concentration and also due to the competition of both cations.

The major cause of cation exchange property of chlorite arises in the broken bonds on non-cleavage surfaces. That the plot of  $K_d$  versus  $R_{Mg}$  passes the origin without observable adsorption on the broken bonds at  $R_{Mg} = 0$  may be the result of complete saturation of these bonds in the case of marine sediments.

For the other metal ions tested, namely, strontium, cobalt, and europium, no such relations could be found, as was in the case of the marine sediments. Therefore, exchangeable potassium and exchangeable magnesium, respectively, in montmorillonite and in chlorite, play an important part in the adsorption of caesium. Furthermore, two other montmorillonite samples found from different localities, for which particle fractionation was impossible, were missing on the straight lines obtained in Fig. 1. This fact suggests the importance of the clay mineral structure, especially the number of broken bonds, and the chemical composition.

## PSYCHOLOGY

## Vocalization-at-presentation, Auditory Presentation and Immediate Recall

PREVIOUS work<sup>1</sup> has shown that if subjects performed increasing degrees of vocalization on a visually presented list of 8 consonants, recall of that list improved monotonically as vocalization level increased. Thus voiced lists were better recalled than whispered lists, whispered lists than mouthed lists and mouthed lists than silently perceived lists. The relative efficiency of voicing as regards its effect on recall was greatest for lists presented at fast rates (4 letters/sec); written recall was also found to be superior to spoken recall, although there appeared to be no significant interaction between vocalization level at presentation and the mode of recall (spoken against written).

At first sight these results might seem to indicate that the 'more' one responds to a list at presentation, the better will be recall. However, there is an alternative hypothesis. It might be that auditory presentation *per se* is particularly good for immediate recall purposes, and that the advantage of vocalization may be put down to the addition of an auditory message to the visual message given at presentation. One way to test this would be to reduce the subject's ability to hear himself, by concurrently presenting white noise. Such an experiment will shortly be reported; but we also need some more objective evidence concerning the efficiency of auditory presentation on immediate recall. In the work to be described, we shall compare the recall of lists merely seen with that of lists merely heard, and in addition compare the recall of voiced lists (self-produced auditory stimulation) with that of lists seen and simultaneously heard as spoken by the experimenter (externally produced auditory stimulation). If it were true that the degree of overt activity were the main determinant of vocalization's advantages for recall, we should expect self-produced auditory stimulation to give superior recall to that for externally produced auditory stimulation. On the other hand, if simply obtaining an auditory message were the main determinant of recall, there should be little difference between the two conditions, and in addition lists merely heard should be better recalled than lists merely seen. It should be noted that examination of the available literature<sup>2,3</sup> does not give a clear-cut answer to the question of whether visual or auditory presentation is superior for immediate recall: their relative efficiencies appear to vary, for example with age or intelligence<sup>4</sup>, although more recent work by Buschke<sup>5</sup> has suggested that auditory presentation is superior to visual presentation for immediate memory as measured by a recognition method. The results of Henmon<sup>6</sup> should be particularly noted, however: he found that the recall of 10-item lists of digits or nonsense-syllables was best if they were merely heard, and that there was little difference between self-produced and externally produced auditory presentation as regarded immediate recall, but only 6 subjects were used.

The technique used in the present experiment has been described previously<sup>1</sup>. Subjects saw lists of letters presented one at a time through the viewing-slit of a screen covering a continuously moving roll of paper on which the letters were printed. In each list there were eight consonants (all different, selected according to a random procedure), and the presentation-rate was set at 1.33 letters/sec. for all lists. A typical list was LVMKTNOS.

Two presentation-conditions used previously were used again. As the letters were presented, subjects either: (i) merely looked at each letter as it appeared (condition *R*—read) or (ii) looked at, and also voiced aloud, each letter (condition *V*—voice). In addition, three new conditions were used: (iii) *S* covered up the viewing-slit and merely heard the letters read out to him by *E* (condition *A*—auditory); (iv) *S* both saw the letters and simul-

taneously heard them read out by *E* (condition *RA*); (v) *S* first saw each letter and, about 0.4 sec later, heard it read out by *E* (condition *RA*<sup>+</sup>). The purpose of *RA*<sup>+</sup> was to make the situation of seeing and hearing more analogous to that of voicing; when a subject voices a letter, he hears his voice a vocal reaction-time (approximately 0.4 sec)<sup>6</sup> behind his initial perception of the letter.

Concerning these various presentation-conditions: *R* and *V* have been described. Condition *A* was achieved by simply covering up the viewing-slit, while *E*, concealed behind a screen, read out the letters as he himself saw them through a set of mirrors arranged about *S*'s viewing-slit. For condition *RA*, *E* also read out the letters, though this time they were in addition visible to *S*. For condition *RA*<sup>+</sup>, the delay of *E*'s voice was arranged by preliminary trial-and-error to coincide as exactly as possible with *S*'s own vocal reaction-time. The interval was found by moving a bar across one of the mirrors to a position such that if *E* read out the letters as they crossed the bar, his voice coincided with *S*'s own voice as *S* read out the letters. (In the actual test, of course, *S* did not voice on condition *RA*<sup>+</sup>.) With a presentation rate of 1.33 letters/sec, *E*'s voice never coincided with *S*'s perception of the next letters in the list.

Recall was given immediately after having perceived the eight letters, *E* having switched off the machine. The recall was either spoken into a tape-recorder, or written on prepared answer-slips; *S* could recall in any order, provided he specified the original positions of all letters recalled. If a letter could not be recalled, *S* could omit or guess as he preferred.

Twenty male adult subjects (mainly students) were used, all of whom had taken part a year previously in an experiment in which conditions *R* and *V* had been investigated. Thus they were highly practised at the general task, but were not familiar with conditions *A*, *RA* or *RA*<sup>+</sup>.

Table 1 shows the percentage correct of the total possible number of letters on each of the conditions. Each letter was marked as correct only if it appeared in its correct position in the presented list.

Table 1

	<i>R</i>	<i>RA</i>	<i>RA</i> <sup>+</sup>	<i>V</i>	<i>A</i>	Mean
Spoken recall	57.27	64.37	66.90	65.63	68.44	64.50
Written recall	69.45	78.06	77.81	77.27	79.09	76.45
Combined recall	63.36	71.21	72.45	71.45	74.06	70.45

Analysis of variance applied to the raw data showed that the vocalization, recall-method, and 'subject' factors all gave variance-ratios significant at  $P < 0.001$  ( $F=8.08$ , 132.0 and 12.76 respectively). In addition, the interaction between vocalization and subjects was significant at  $P < 0.05$  ( $F=1.56$ ); the interactions, vocalization with recall-method and recall-method with subject, were not significant. Tests by the method of orthogonal comparison<sup>7</sup> showed that the difference between the 'combined' totals of *R* and *RA* was significant at the 0.01 level ( $F=22.78$ ) and that the difference between *RA*<sup>+</sup> and *A* was not significant ( $F=1.14$ ). It can be seen that there were no significant differences between *RA*, *V*, and *RA*<sup>+</sup>; and that the difference between *A* and *R* was significant at a level of at least  $P < 0.01$ .

It therefore appears that: (i) it made little difference for recall-purposes whether the auditory stimulus was self-produced (*V*) or externally produced (*RA*, *RA*<sup>+</sup>); (ii) merely hearing the list (*A*) gave recall insignificantly superior to both hearing-and-seeing and voicing, and significantly superior to merely seeing (*R*); and (iii) in the *RA* conditions, it made little difference whether the heard letter coincided with, or was slightly behind, the seen letter. These results are very similar to those of Henmon, and they hold both for spoken and written recall, although the latter gave significantly superior recall overall.

The implication of the findings, we suggest, is that although adding cues to the visual message was of assistance

tance, optimum performance was obtained when cues were presented entirely in the auditory modality. The advantage of vocalizing may therefore be hypothesized to rest partly on the fact that more cues were in general available to *S*, but more particularly on the fact that *S* was presenting himself with a cue in a preferred modality, that is, auditory. Introspective evidence obtained from the *S*'s supported this, and also suggested that *A* gave (insignificantly) superior recall to *RA*, *RA*<sup>+</sup> and *V* because *A* provided less 'distraction' during the task of perceiving and storing the presented list. The fact that *S*'s were already highly practised at *R* and *V* lends greater force to the present finding that pure auditory presentation gave recall at least as good as voicing-at-presentation. Why auditory immediate memory should in fact be so efficient—at least under the conditions described here—remains to be answered. It should be noted that the significant interaction of subjects with vocalization suggests that there might be an important element of individual variability as regards preference for one presentation-method or another.

This work was done while I held a studentship at Trinity College, Cambridge. I thank A. J. Watson and Prof. O. L. Zangwill of the Cambridge Psychology Laboratory for their advice and encouragement, and Dr. A. G. Worthington of the Psychology Department, Queen's University, for statistical advice.

## Effects of a Drug and Immediate Memory

A NEW test of immediate memory was recently suggested by Buschke<sup>1</sup>. *N* - 1 items drawn from an ensemble of *N* are presented, and the task is to name the missing item. An experiment is described in which this technique, the 'missing scan method', was used to evaluate the effects of sub-anaesthetic doses of nitrous oxide on immediate memory. The results seem to cast light on underlying processes. It is suggested that two forms of storage may be distinguished—that used depending on the presentation-rate of items—and that one form is especially susceptible to drug effects.

Random auditory sequences, each consisting of seven letters drawn from the ensemble A-H, were presented at two rates: two items per sec (fast), and one item every 2 sec (slow), to subjects fully equilibrated under low doses of nitrous oxide. Practice sequences were given during induction of the gas. Sixteen student and technician volunteers (aged 18-33), used as their own controls, received 15, 25 or 35 per cent nitrous oxide and air (control) on successive days according to a 4 × 4 factorial design. Dose-effect curves for errors and latencies of correct responses (geometric means) are shown in Figs. 1a and b respectively.

There was no evidence of impairment of performance accuracy in the 'fast' condition up to and including the 25 per cent dose, but in the 'slow' condition as little as 15 and 25 per cent nitrous oxide increased errors significantly (2-tailed Wilcoxon tests, *P* < 0.01; *P* < 0.05 resp.). Thus,

since disruption of stimulus registration by the drug should result in a greater drug effect at faster rates, there was no evidence of a drug impairment of this stage. A drug effect on retention is therefore suggested. There were no significant differences between the input conditions under any dose of nitrous oxide. But under air there were fewer errors at the slower rate (2-tailed Wilcoxon, *P* < 0.01). The results are therefore not consistent with a simple trace decay theory, since under air control subjects did better when they had to wait longer before responding. The drug appears to have disrupted some process in the 'slow' condition. The results suggest some sort of interference with memory traces and resemble Fraser's<sup>2</sup> findings on the effects of ageing.

Fig. 1. a, Dose-effect curves for errors; b, dose-effect curves for response latencies. Rates of presentation. ●, fast; ×, slow

As Figs. 1a and b suggest, accuracy of performance in the 'slow' condition was prone to drug impairment, response latency was not. In contrast, accuracy in the 'fast' response was resistant to impairment (except at the highest dose), but latency increased progressively with dose (Jonckheere trend test; *P* = 0.012). The longer response latencies for the 'fast' rate should be noted: the difference between the conditions was very highly significant (analysis of variance on mean log latencies; *P* < 0.001).

Introspective reports seem relevant in accounting for the latency difference between the 'fast' and 'slow' rates of presentation, and in explaining why the two input conditions were differently affected by nitrous oxide on the two performance measures. Subjects reported that in the 'slow' condition they formed a spatial image of the ensemble and had time to cancel each item as it arrived, so that at the end of presentation they had only to 'read out' the missing item. Many reported that the drug tended to interfere with this image. In the 'fast' condition, subjects reported that the items arrived too fast to cancel as they occurred, and were first stored as sound, being transferred to the spatial image at the end of presentation.

Assuming the introspective evidence of two separate stores is valid, the latency data imply that the time for transfer of the items from the first to the second store was normally about a second, and that it was progressively increased by nitrous oxide. The error data suggest that the second store may normally be the more efficient, but is especially vulnerable to drug effects.

Further work is in progress to evaluate this two-store hypothesis of immediate memory. Drugs promise to be a useful tool for this purpose.

This work was supported by grant MH-03313 from the U.S. Public Health Service, and was carried out under the supervision of Prof. Arthur Summerfield and Dr. Hannah Sternberg.

## SCIENCE, THE CREATIVE ART

IN scope and in calibre Sir Cyril Hinshelwood's presidential address to the British Association for the Advancement of Science (see p. 1055 of this issue) resembles his earlier presidential addresses, to the Chemical Society at its centenary meeting, and at the tercentenary of the Royal Society. Indeed, to read it in the context of those addresses quickens one's appreciation of Sir Cyril's understanding of the wider audience which he is addressing at Cambridge, the skill and imagination of his exposition, and the challenge of his message: "Science, whatever else it may be, is a form of creative art". Sir Cyril seeks to commend this view of science to society at large by brief glances at some outstanding scientists of the past generation and finally by looking at the way in which scientists to-day are facing the oldest and most absorbing questions of all: the nature of the cosmos, the nature of matter, the nature of life. Passages in his address recall an address on "Science for its Own Sake", which his predecessor, the late Sir Edward Appleton, delivered twelve years ago (*Nature*, 172, 424; 1953). However, Sir Cyril's approach and treatment are all his own, and he does not pursue the theme of science as an artistic and human value further than to illustrate the nature of scientific activity.

He begins at the level of ordinary life. Science, he reminds us, is no longer a private affair but a public concern, and he touches surely on some of the practical implications of the new situation, particularly of the wider general interest in applied science than in pure science. The relation between the two is exceedingly subtle and complex and Sir Cyril attempts no definition of either pure or applied science. He is content to remind us of their interdependence and of the folly of insisting that all scientific effort should be devoted to demonstrably practical ends. We cannot be reminded too often that Nature in her own time reveals her secrets to the patient questioner, and is infinitely cleverer than man. Science cannot be dismissed as a polite amusement, and it would indeed be a tragedy if people with a real vocation for science were seriously diverted in the supposed interest of utility.

What does disturb Sir Cyril is that few of the large numbers of recruits to science seem to evince the interest in technology for which the future calls. For this situation Sir Cyril suggests two factors have been important. First, failure to give science its proper status, either in the Civil Service or elsewhere, has tended to deter all except the minority with a real vocation. Secondly, while the achievements of this dedicated minority have to some extent rectified this position, society has largely withheld its due esteem from practical skills. Furthermore, with this failure to understand the real nature of either science or technology, our educational system has tended to direct into other more remunerative fields precisely those young people whose minds are disposed to ask not so much "Why does this happen?" as "How could this be done?" or "What use could be made of this?"

At this point there is a passage which is liable to be misunderstood. Sir Cyril condemns the unjustifiable primacy which, in our traditional methods of education, selection and promotion, we have accorded to skill in purely verbal expression. It is quite wrong to suppose that all thought is through the use of words: non-verbal

images can be just as important. Some people think with their hands, and Sir Cyril reminds us that we need to give much greater credit to manual skill than we do—except, perhaps, in athletics.

Now this timely reminder of the immense importance of manual skill as a form of expression, especially for the craftsman and the myriad kinds of technician required to support the scientist or technologist, is not to be interpreted as repudiating the need for accuracy of expression. Sir Cyril is too fine a scholar to give any countenance to the disturbing prevalence of illiteracy or slovenliness of expression to be found to-day in universities as well as in schools. He is too skilled an expositor himself to deny to the gifted expositor or interpreter the honour that is his meed, and later in his address he quotes the *obiter dicta* attributed to Rutherford that no physical theory is worth much if it cannot be explained to a barmaid.

What Sir Cyril is concerned with here is not the problem of communication at all but our failure to accord to those who work with their hands the status and prestige that are their due—our tendency to exalt the academic over the practical, to place applied science second to pure science, instead of on an equality. The adventure of controlling Nature, he reminds us, is no less great than that of understanding its deep secrets. The whole climate of opinion in society must change if we are to find the recruits for technology that we need: not all of them will come from science itself; many may well be found in quarters where society has hitherto discouraged the development of any interest in science at all.

Here Sir Cyril's pragmatism is addressed to us all and in it we discern the real motif of his address—an interpretation to the ordinary man or woman of the way in which the scientist works and thinks. He passes then to the organization of research, and here his pragmatism is aimed at the administrator and politician; his words are not always comfortable. In the grand perspective of world history, the interplay of discovery and application has been largely an affair of chance. Those who now wish to guide and plan the process, to rationalize and accelerate it, have to remember that inspiration comes only to rare individuals, floating up intuitively from the subconscious. It is communicable from a leader to a team only if the members have confidence in him, both as a man and as a scientist. There is little place in scientific research for philosopher kings, prescribing broad human objections to teams of docile scientists.

Almost any debate on science or its applications in the House of Commons will indicate how much our legislators need Sir Cyril's warning, how disposed they are to believe that the planning and direction of research is a logical process, proceeding by obvious stages from point to point to a predetermined goal after an expenditure of time and money calculable in advance by accountants. On the contrary, as Sir Cyril says, if we wish to plan research we can only do so by assembling a community of people with varied and mutually complementary talents, operating with strategic flexibility, and in an atmosphere of curiosity in which the members know and understand what the others are talking about and respect their leaders. At a time of considerable change in our organization of civil science, it is particularly easy to forget that an

honoured place must be found for the dedicated thinker and that no committee structure can replace such devotion.

Sir Cyril's warning here is emphatic and is reiterated. A scientific community cannot be led either by people uninterested in human relations or by professional humanists without real personal understanding of what science involves. His prescription for future success in applied science is humane enough: a well-assorted community of human types, including the analytical, the creative, the enterprising, and the manually dexterous, all enjoying equal status, so that each part of the task may be taken up by some when others have made their contribution, and all familiar with the rudiments of the same language—the general idiom. Nevertheless, the advance of discovery and science cannot be speeded up merely by administrative elaboration or by imposing political doctrines. Creative scientific research remains a very difficult business and its application is both adventurous and laborious, demanding not only courage and skill but also faith. If its spirit is to spread widely from the relatively few individuals of the past then the whole climate of society must be favourable.

Once again we hear Sir Cyril's leitmotif and now it leads him to discuss how scientists work. Just as firmly as Sir Edward Appleton did, he insists that science is one of the great activities of the human mind and soul, and he adds that, in the last resort, society was made for man and not men for society. It is in this connexion that, like Sir Edward, he quotes the words which Dante long before put into the mouth of Ulysses when he encouraged his companions to venture with him, beyond the furthest point of the known world: "You were not born to live like the beasts, but to strive after virtue and knowledge". Sir Edward, however, quoted more fully and also applied to the scientist seizing his opportunities the words with which Tennyson closed his picture of Ulysses:

"... yearning in desire  
To follow knowledge like a sinking star,  
Beyond the utmost bound of human thought . . ."  
"To strive, to seek, to find, and not to yield."

Sir Cyril, however, passes on to make his point from a brief reference to the lives of three Nobel laureates in physiology—to Pavlov, Ramón y Cajal and Sherrington. He shows that with differing background, temperament and tastes, the trio shared a common passion for knowledge, for discovering things previously unknown, and for unravelling mysteries, and that they also shared an essentially aesthetic appeal in their work. He pauses also to note, just as Appleton did before him, that this is true of most other scientists, and then goes on to drive home his point that science is a creative activity by glancing briefly at the lives of some great physicists of roughly the same generation—at Max Planck and Einstein, at Eddington and Rutherford.

The creative scientist, Sir Cyril observes, is usually more concerned with the relations of things one to another than with the precise verbal analysis of what these things are. He seeks a representation of the world which grows continually by an extension or transformation of what is there already. What many scientists are really after is the adventure of discovery itself, and, referring to Rutherford's belief in the imminence of wonderful new revelations about to occur as amply warranted at the present time, Sir Cyril brings us back to Newton himself, not indeed to:

"... a mind for ever  
Voyaging through strange seas of Thought, alone".

but rather to his words when asked how he made his discoveries, and he replied: "By always thinking unto

them. I keep the subject constantly before me and wait till the first dawnings open little by little into the full light".

That quotation might well be regarded as the key passage in Sir Cyril's address, for when finally he refers briefly to some of the fundamental problems of science which are of the deepest significance in their own right, it is more to display the approach of the scientist than to illumine or even expound the problems themselves. Let it also be noted that Sir Cyril reminds us that the study of these problems, if history has any lessons to impart, will in the long run have the greatest effect on human life; however, he is careful to make no reservation as to the urgency of other work of shorter range. Even with Hamlet's wise warning to Horatio, and without straying into the abstruse, he shows how lively imagination continually plays on a stream of new discoveries wherever man is thinking about the problems of existence—of the structure of the universe, of the structure and properties of matter, or of the physics and chemistry of living matter.

At all the boundaries of science, he reminds us, we confront what are probably the inherent limitations of human understanding. At the edge of biology we meet the chasm between what science describes and what the mind experiences. In the physical sciences we encounter insoluble contradictions if we try to contemplate the limits of space, or the beginning of time. Nevertheless, the men of science, as depicted by Sir Cyril, are not perturbed by the limitation of their possible understanding. There seems to be no foreseeable terminus to their adventure. If the canvas on which they represent the world is bounded, it has room enough for them to paint pictures which can inspire the enquiring mind, can delight those who have the sense of wonder, and can show the way to benefit humanity for many centuries to come.

The question is whether the natural perversity of man may quench that inspiration or spirit of enquiry, crush or kill the sense of wonder, or block the way, and it is on that cautionary note, with its implications, perhaps especially for the educationalist, the administrator and the politician, that Sir Cyril closes. It is probable that only those who have themselves been concerned with scientific research will appreciate all the fine nuances of Sir Cyril's address, but the picture he paints of the scientist as a creative worker, of the need for freedom of expression and appropriate conditions of work, and of public understanding if his work is to be fully effective, is intelligible to any layman. It is no picture of a scientist working and living in some 'ivory tower', or even of Thomson's Newton, "stemming alone vast eternity's unbounded sea", but rather of a happy voyager of strange seas of thought, in company with others trained in the same or many other disciplines. Nor is the picture the less sharp in that Sir Cyril paints it with scarcely a reference either to the particular discipline of which he is himself so eminent a practitioner or to the research group or team. It is above all a picture of a thinker, but not of one to whom Pascal's words apply: "Le silence éternel de ces espèces infinies m'effraie", but rather of the Pascal who added, on reflection, "Toute notre dignité consiste en la pensée". If science is an essential means to an understanding of the forces of the universe or an element in forming any worthy and adequate view of life, it must be understood and treated as such, for only as it flourishes can man know and do aright and steer onward to some purposed haven.

## THE CAMBRIDGE REGION

## The Cambridge Region 1965

Edited by Prof. J. A. Steers. (Prepared for the Meeting of the British Association held from 1 to 8 September, 1965.) Pp. xv + 249 + 12 plates. (Cambridge: Cambridge Local Executive Committee of the British Association for the Advancement of Science, 1965.) n.p.

*THE Cambridge Region 1965* has been specially prepared by the Cambridge local committee of the British Association for the Advancement of Science and edited by Prof. J. A. Steers. Its aim is to provide background information on the region for those who are visiting Cambridge for the annual meeting of the Association. The Publications Committee considered that many people, in addition to members of the Association, would be interested in having a book giving an account not only of new work which has produced different ideas about the interpretation of the district (rural and urban), but also of new views ranging, for example, from those concerned with education to those on the economics of farming or on the scientific investigation of the raw materials of pre-history, since the Association last met in Cambridge in 1938. Essentially, then, the emphasis is on change.

Eleven chapters have been provided by twenty-two contributors and should give the visitor a good picture of the Cambridge region. First to be described are the geology and ground water, then in logical sequence: relief and drift deposits; flood protection and Fen drainage 1939-64; natural history; soils; agriculture; archaeology; Cambridge and its regional setting; education in Cambridgeshire; the University of Cambridge; aspects of development 1938-65; research and industry in and around Cambridge.

Of special interest to the geologist are the outcrops of Jurassic and Cretaceous rocks; however, results of bore-hole work carried out in the early 'fifties have thrown much interesting light on the hidden Palaeozoic floor. Within the region representatives of the Oxfordian and Kimmeridgian zones of the Jurassic are present, while for the Cretaceous there are the Lower Greensands, the Gault Clay and Lower, Middle and Upper Chalk. Concomitant with these the ground waters of interest are the chalk waters and the Lower Greensand waters. Throughout the chapter extensive references are given to the relevant Geological Survey New Series 1-in. sheets. There is, perhaps, a case for presenting a general geological map of the region in these handbooks because many of the amateur geologists will not necessarily have access to the Survey maps.

The major elements of relief within the basin of the Cam and that of the Great Ouse below Huntingdon are the Fen islands (now drained) and the associated Fen margins. Spread over these are sheets of boulder clay (till) and ribbons of river silt (roddons). These are described and discussed in Chapter 2, together with the problem of the age of the widespread till. Also outlined are the evidence for, and history of, glacial events in the region, including pre-Gipping relief and deposition, the Gipping glaciation, physical events of the last interglacial period, the last glaciation and its effects, and, finally, the post-glacial period.

Only 2 million acres of England and Wales (or just more than 5 per cent of the total area) is classified as first-class arable land. The majority of the Fenland area comes within this classification. Chapter 3 briefly outlines the history of the Fens since their reclamation during 1630-52 by the fourth and fifth Earls of Bedford—"A doleful catalogue of disasters, interspersed by brief intervals of triumph". The story for the 1939-64 period is certainly a sorrowful one of floods, war and Government red-tape, but one which gradually brightens as contract work gets under way and is completed on the relief channel, the widening and deepening of the Ely Ouse and Ten Mile Rivers, and the out-off channel with follows around the

eastern margin of the Fens. It is interesting to learn that there is scarcely any gravity drainage from the peat lands and that the rivers flow in normal times some 6-12 ft. above the Fens behind flood banks.

The Cambridge area had always offered much of interest to naturalists because of marsh and aquatic habitats associated with slow-moving rivers, flooded clay- and gravel-pits, and poorly drained and seasonally flooded meadow and pasture. While engineers, builders, agriculturalists and town planners have been vigorously concerning themselves with land reclamation, flood protection and Fen drainage, the naturalists have been frantically trying to preserve the Fen from drying out, from bush colonization and especially from threat of total drainage and destruction. S. M. Walters, in his chapter on the natural history of the region, emphasizes the frightening phenomenon to the naturalist of taming and urbanizing south-east England and the associated losses of flora and fauna, and he puts forward a strong case for carefully planned conservation.

Three principal soil types determine the main range of surviving semi-natural habitats for plants and animals in the county. The most important of these are the woodlands on heavy clays, the grassland and scrub of the chalk, and the Fenlands. Important examples of all these are protected as Nature reserves or sites of special scientific interest, such as Hayley Wood, Holme Fen, Wicken Fen and Wood Walton Fen. Much of the concern of naturalists has inevitably been with the rarer species, particularly when its continued existence in a particular locality is threatened. However, it now seems that, besides the red squirrel, the frog, the rabbit and the kestrel are becoming increasingly scarce. Newcomers to the region include the grey squirrel, the coypu and the collared dove, and among the plant kingdom, the willow herb, *Epilobium adenocaulon*, and the moss, *Orthodontium lineare*.

The present regional handbook has been carefully prepared so as not to repeat what was written in the survey prepared for the 1938 meeting. In the latter the soils of the area were viewed from a mainly agro-geological point of view. Chapter 5, "Soils", gives emphasis to the genesis of the soils and their relationship with broad world groupings. In 1950 the Soil Survey of England and Wales undertook the preparation of a detailed map of the country immediately north-east of Cambridge and this was published in 1963. The present chapter is accompanied by a coloured soil-map of the region at a scale of 1:250,000. Soils of the district are classified into seven groups: podzolized soils; brown earths; calcareous soils; grey soils, warp soils; immature soils; organic soils. Of special interest are the Fen peats and Fen silts. Essentially these are artificial, for the water-level has been controlled by the drainage measures of the past 300 years. Drainage of the peat led to considerable shrinkage, which reached a maximum of about 10 ft. Fen silts are marine and estuarine deposits which at present are being laid down most rapidly on the southern margin of the Wash where the silt is trapped by salt-marsh vegetation. For purposes of land reclamation a new sea-wall is constructed when a reasonable area of marsh of a suitable surface texture has accumulated to a height of about 10 ft. O.D.

Agriculturally the Cambridge region is characterized by high dependence on crops for sale, as compared with live-stock products. Chapter 6, by means of plentiful illustrations and tables, makes it obvious that cash crops in the region are about ten times as important as grazing livestock. It shows that the region provides a major percentage of the total production in England of, for example, brussels sprouts (25.1), celery (42.1), gooseberries (25.4), carrots (18.7), sugar-beet (14.0). For descriptive purposes the region is divided into six farming areas: (1) south-east Cambridgeshire (40 per cent of the region's crops and grass); (2) east Bedfordshire (market gardening); (3) west Cambridgeshire and Huntingdonshire (crops, beans and peas); (4) Ely Black Fens (potatoes and

sugar-beet); (5 and 6) Cottenham and Wisbech (fruit-growing). Since 1938 the agricultural picture has developed as one of greater output, produced by fewer men but more machinery and fertilizer and with more land under the plough—the barley acreage has increased nearly four-fold and now represents 28.2 per cent of the region's total crops and grass.

The region is well endowed with organizations concerned with agricultural research and advice—including the Agriculture and Veterinary Medicine Departments in the University of Cambridge, the National Institute of Agricultural Botany, the Veterinary Investigation Centre, the Agricultural Research Council Institute of Animal Physiology and the Plant Breeding Institute, the Ministry of Agriculture's Experimental Husbandry Farms, and the Poultry Research Station—all of which play an important part in the agricultural efforts of the region, and of the nation as a whole. The final section of the chapter deals with some current developments and problems, including high cereals rotation, mechanization, maintaining healthy crops and farm management.

In the chapter on the archaeology of the Cambridge region, only discoveries made and work done since 1940 are mentioned specifically; however, an attempt has been made to incorporate more traditional material in discussions on particular points. The first part of the chapter deals with "Prehistory" and here the emphasis is on results gained from the application of various sophisticated scientific aids which have become available to help the prehistorian in dating, identification and interpretation. Radiocarbon dating is being undertaken on the Upper Palaeolithic industries near Mildenhall. Recent work on the Mesolithic of the British Isles has clarified the picture of this phase of early settlement and has been greatly assisted by the work of Prof. H. Godwin in the zoning of post-glacial deposits by pollen analysis. An important site at Peacock's Farm, Shippea Hill, known to have a Neolithic occupation, has been studied and pollen and radiocarbon analyses carried out. (This particular piece of work has helped to show that the British Neolithic is older (3400–3000 B.C.) than was previously assumed.) Metallurgical studies of artefacts and copper sources from Bronze Age sites have been carried out and various metal objects have been subjected to optical emission spectroscopy: results gained have thrown much new light on the origin of the various ores used. Several Iron Age sites, including the Wandlebury hill-fort, have been surveyed by means of proton-magnetometers and successfully excavated on the basis of this. The second part of the chapter deals with "The Romano-British Period". In this is described recent work carried out in tracing the Roman road and water systems of the area. Numerous successful excavations are reported on settlements, defences and farmsteads. Much new material has been unearthed including mosaics, pottery, pewter tableware, bronze and glass jugs, figurines, bracelets, etc.

"Cambridge in its Regional Setting", by far the longest chapter in the handbook, is divided into three sections which deal with: (1) "The Cambridge Region: Settlement and Population"; (2) "Cambridge: its Origin and Growth"; (3) "The Modern City: Future Trends". The first section constitutes almost half the chapter. The problems of Cambridge are intimately bound up with those of south-east England as a whole, and the relationship with London is of particular importance and significance at the present time. Cambridge has unquestionably taken dominance as the regional centre. Surrounding it is a ring of small market towns; but the clarity of this pattern is lost in the Fenland and around its margins. The variety of rural settlement is considerable and ranges from dispersed and substantial farmsteads, standing alone in fields of a large holding, or the isolated bungalow of a Fenland smallholder to the big villages and market towns which are to be found near the margins of the Fenland. The various patterns of settlement in the area not only

depend on the way in which the area was initially colonized from Anglo-Saxon times, but also on subsequent changes in population and economy. In the Fenland the difficulty of finding firm sites for building and the chronology of reclamation are important factors affecting the pattern of settlement.

Cambridge is situated on a meander of the River Cam and, as the second section of Chapter 8 shows, it is the particular situation of the site that has given Cambridge its especial importance. It lay in the angle between the prehistoric bundle of tracks, the Icknield Way and the Roman Road, Ermine Street. East Anglians journeying from Colchester or Ipswich or Norwich to the Midlands found their easiest way skirted the southern edge of the Fenland and crossed the Granta (Cam) Valley in the neighbourhood of Cambridge. It was the Romans who, in building their roads, gave pre-eminence to this crossing. In times of the Anglo-Saxon invasion Cambridge gained strategic importance. An entry in the *Anglo Saxon Chronicle* for A.D. 875 records the name 'Grantebryce': this indicates that the ford had been replaced by a bridge (it is the earliest known recorded use of the word 'bridge'). It was this bridge that enhanced the importance of the little settlements beside it, and in due course 'Grantebryce' became the administrative centre of the region and a market town. To this thriving centre came first the mendicant orders, then the teachers and scholars. The origins of the University are obscure. In 1209, however, a group of scholars arrived from Oxford, probably attracted by teachers already famous. Little land was at first needed, teachers and pupils lived as and where they could; but as their numbers increased hostels, halls, then colleges were founded—land being purchased or acquired by gift. During the thirteenth-sixteenth centuries, and in the nineteenth century, more and more colleges were founded and little by little Cambridge took up the form that it has to-day.

In his section on the "Modern City", A. A. L. Caesar discusses a problem only too well known to many present-day town planners in Britain. The problem is one of planning for a growth of population and a car-owning population, but this related to the lay-out of a historic centre. The twentieth century has brought to Cambridge, as elsewhere, a great acceleration of change, and one of the most conspicuous forces responsible for this has been the great development in transport. While facilities in Cambridge were sufficient until about the 1920's, a crisis point has now virtually been reached. Mr. Caesar puts forward his case with great care and clarity and sees long-term planning as the most important aspect of the remedy. Planning, he feels, should be in terms of 2065 rather than of simply answering the immediate problems of 1965. Commercial and domestic buildings may well have a life-span of 100 years, but street lay-outs tend to be less durable. He discusses the pros and cons of pedestrian precincts, road development and a new main shopping area. He describes the projected redevelopment of the City Road and Lion Yard areas. Cambridge as he sees it stands poised—choosing, weighing new ways. However, as he states, it cannot pause for long: plans must be made and implemented if growth unplanned is not to be wholly destructive.

The various facets of the Cambridgeshire educational scene are described by eight authors in Chapter 9. As a result of the Education Act of 1944, the Cambridgeshire County Council became the Local Education Authority for the whole county. In 1965 the two Authorities for Cambridgeshire and the Isle of Ely were amalgamated. So far as an adequate supply of teachers is concerned, Cambridgeshire, because of its many amenities, is fortunate compared with many parts of Britain. The distinctive feature of secondary education in the region is the Village College—a combination of secondary modern school and a community centre providing for the education, social and recreational life of the rural area. The first of these

was founded in 1930, and since then ten in all have come into being.

Recently, considerable effort has gone into putting into practice many of the recommendations of the Newsom and Robbins Reports. Audio-visual aids, including very-high-frequency radio, television, record-player, projector and tape-recorder, are having an ever-increasing role in school teaching. The Authority has endeavoured to encourage an atmosphere of experiment and enquiry in the junior schools. Developments within the rural area and the City are described together with the role of technical colleges, farm schools, youth employment schemes, and psychological and remedial services. Also described are the direct-grant and independent schools, University extra-mural teaching, and the parts played and the work done by the Eastern District of the Workers' Educational Association, the University Department of Education, and the Cambridge Institute of Education.

In the twenty-seven years since 1938, numerous changes have occurred in the University of Cambridge. New buildings have been erected to accommodate overflowing departments and house new research efforts. Two new colleges, New Hall for women, and Churchill for men, have been founded. A third, Darwin College, has recently been established: this is an innovation in that it is restricted to graduate students. The undergraduate population has increased 50 per cent since 1938, and this has been accompanied by a corresponding growth of the teaching staff. The strain on the Colleges has been threefold: accommodation, facilities and adequate teaching for more undergraduates; adaptation to meet the needs of research and other graduate students; expansion of the number of fellowships. Since the Second World War a new structure of university stipend has been introduced, and the holder of a university office no longer simply depends on the stipend from his College. A number of new forms of tripos have been introduced, and many have been, or are in the process of being, revised. New post-graduate diplomas relating to agriculture, criminology, estate management, mathematics, etc., have been introduced. A movement is at hand to introduce a new degree (M.Phil.) for award on an examination based on a 2-year course of advanced study in a specialist field. Chapter 10 ends by briefly directing attention to some aspects of research at Cambridge, including computer work, radio-astronomy and macromolecular biology.

Cambridge remains a university town and market centre for one of the least-industrialized regions in Britain. However, a number of science-based industries and industrial or government research stations have grown up or been attracted to the district. Chapter 11 gives brief accounts of the history and work of the various organizations. First, the industrial concerns are dealt with under: chemicals and plastics; electronics and instruments; metallurgical and engineering; other research organizations. Under the heading "Government Science" are described the various units in the region which are the responsibility of the Agricultural and Medical Research Councils. These have relationships of various closeness with the corresponding departments within the University.

It is pleasing to note that most of the chapters have been provided with a list of references and that an adequate index has been prepared—the latter is something which has been absent from many of the British Association regional handbooks in recent years. The one criticism that can be levelled at the present publication is that a general map has not been provided. Certainly this would have helped considerably to bring together the various themes which are presented. In any event, Prof. Steers and his colleagues are to be congratulated on preparing a well-balanced account of the Cambridge scene and its development over the past twenty-seven years.

R. J. FIFIELD

## THE COMPLEAT PHYSICIST

### Encyclopaedic Dictionary of Physics

Editor-in-Chief: J. Thewlis; Associated Editors: R. C. Glaze, D. J. Hughes (deceased) and A. R. Meetham. Vol. 2: Compensator to Episcadmium Neutrons. Pp. ix+880. Vol. 3: Epitaxy to Intermediate Image. Pp. ix+804. Vol. 4: Intermediate State to Neutron Resonance Level. Pp. ix+836. Vol. 5: Neutron Scattering to Radiation Constants. Pp. ix+782. Vol. 6: Radiation Continuous to Stellar Luminosity. Pp. ix+883. Vol. 7: Stellar Magnitude to Zwitter Ion. Pp. ix+866. Vol. 8: Subject and Author Indexes. Pp. viii+498. Vol. 9: Multilingual Glossary. Pp. xvi+988. (Oxford, London, New York and Paris: Pergamon Press. Vols. 2, 3, 4, 1961; Vols. 5, 6, 7, 1962; Vol. 8, 1963; and Vol. 9, 1964.) £108 net per set of 9 volumes.

AN encyclopaedic dictionary of physics is fundamentally a new concept. The only comparable work is that produced by Glazebrook and called the *Dictionary of Applied Physics*; but the present work is a great deal larger than this: it has tried to cover all concepts in physics. Individual editors have been chosen for the various parts of physics, but ultimately, of course, there are no sub-divisions in the completed work, since the entries are arranged in alphabetical order. They form a series of articles of not more than 2,000 words, each written by a specialist whose name is given at the end. Many of the entries are, of course, very much shorter than this; for example, a rheostat is defined as "a resistor whose resistance can be varied".

Almost all the articles are excellent. Since it is known who has written each one they are readily acceptable as authoritative, and those that I have had occasion to refer to have proved to be so. They are written at a very reasonable level. Nowadays most authoritative works, such as the *Reports of Progress in Physics*, tend to be too long and detailed; the articles in this *Dictionary* come straight to the point, are short enough for the authors not to be tempted to become too sophisticated, but are long enough for quite specific information to be given. They are certain to be extremely useful for practising physicists (for example, external examiners) who are called on to deal occasionally with subjects outside their own fields. For example, I consulted an article more or less at random: the entry "Shock Wave" describes the nature of these waves, including a historical discussion; it is purely qualitative, and contains no mathematics, although the relevance of mathematics is indicated. Different types of shock waves are then discussed; there are sections on oblique shock waves, and on conical and spherical shock waves. The entry is illustrated by eight figures, gives references to other relevant entries in the dictionary, and concludes with a bibliography of six other works that could be consulted. In addition, one finds that the previous entry—"Shock Tubes"—is also relevant. Throughout the work associated subjects tend to be together for this sort of reason.

It is not easy to discover any real defects in the work. One cannot examine every entry for accuracy. The policy on definitions does not seem to be consistent; some are included, but others are absent; for example, the Maxwell is defined, but not the Weber or the Newton. The older physicist is sometimes at a disadvantage because so many new terms have been introduced since his undergraduate days, and concise definitions would not have taken up a great deal of space.

Some articles—for example, theodolites and complexes (chemical)—seem rather out of place in a work on physics; but one appreciates that it is difficult to draw a hard-and-fast line at the borders of the subject. Certainly, a casual glance through the various volumes does not indicate any undue emphasis on non-physical concepts.

There is little that appears to be quite wrong. The article on the Schmidt lens is useless; it is not a lens but

a correcting plate for a spherical mirror, and no mention is made of the important fact that it is placed at the centre of curvature of the mirror. The article on mirage is rather absurd, and can only be understood if one knows what the author is trying to say; several physicists completely misunderstood it. Obviously an entry in a dictionary is useless unless it can be immediately understood.

The *Dictionary* is not intended to act as a work of reference for values of physical quantities. Only a few tables are given—for example, constants of the solar system and the periodic table—but generally the work must be regarded as a set of explanations rather than of details. This point is illustrated particularly by the various mathematical functions included; they are, of course, generally of interest to physicists, and the emphasis is on explanation rather than on numerical values. For example, those interested—as most physicists are—in probability theory will find compact articles on such topics as the Poisson distribution, stochastic processes, regression line and the error function.

On the other hand, there are also articles on severely practical matters. There is an article on photographic darkrooms, and this shows plans of a standard darkroom with layout of benches and sinks, and gives an indication of the ancillary apparatus required. Another entry deals with laboratory design; this is quite short, but gives a useful collection of eight references at the end.

The complete encyclopaedia consists of nine volumes. Seven of them are of the form which has been described; Volume 8 is an index which gives the subjects of the encyclopaedia and also the authors of all articles longer than 500 words; and Volume 9 consists of a glossary of scientific terms designed to help the non-English-speaking users of the *Dictionary*. An ingenious system enables translations of terms to be made from and into five other languages. Each entry in English is numbered in alphabetical sequence, and in five following columns are given the numbers of equivalent terms in French, German, Spanish, Russian and Japanese. These terms are then given in alphabetical sequence in five later sections of the volume. The information will enable a person who knows no Japanese to find the equivalent of a given English entry, but will not enable him to carry out the reverse process unless he knows the order of the Japanese characters.

Publication of this *Dictionary* must be regarded as an important event in the world of physics. No departmental library should be without it. The price is rather high; it comes to about £13 a volume of 1,000 pages; but perhaps this is inevitable when so many different people have been involved. The editors and publishers are to be congratulated not only on producing this handsome and well-balanced work, but also on persuading such an authoritative body of people to write for them.

The first volume of this work was reviewed in *Nature* (193, 411; 1962).  
H. LIPSON

## CENTENNIAL CELEBRATION OF THE NATIONAL ACADEMY OF SCIENCES

### The Scientific Endeavor

Contributed by Melvin Calvin and 23 other authors. (Centennial Celebration of the National Academy of Sciences.) Pp. vii+331. (New York: The Rockefeller Institute Press, 1966.) 2.50 dollars.

THE settlers from Europe went to America when the new age of scientific endeavour of the seventeenth century was being fostered by the young scientific academies of Italy, England and France. When a more social way of living was established in America they also organized societies for discussions of their observations and experiments.

The American Philosophical Society at Philadelphia was established before the Revolution, and the American Academy of Arts and Sciences was founded in Boston soon after. Benjamin Franklin, Benjamin Thompson (Count Rumford) and Thomas Jefferson were among many colonial Americans who studied science for its own sake as well as for its usefulness. Literate farmers, artisans and tradesmen gathered in scores of local societies for the discussion of science.

By the middle of the nineteenth century there was a growing acceptance of natural science as a suitable subject for teaching in the colleges of liberal arts, and there were increasing numbers of young men who wished to devote all their time to scientific study, teaching and research. The Morrill Acts of 1862 made available grants for the support of colleges of agriculture and engineering and thus emphasized the need for wider diffusion of scientific knowledge as the essential foundation for the development of the national economy. The Civil War showed the needs of the Federal Government for technical advice, and accordingly in 1863, Congress, with the co-operation of fifty scientists, founded the National Academy of Sciences. Promising young scientists went to Europe for advanced study and returned to poorly equipped laboratories and heavy teaching duties that left little time for research. (In less than a century this position has tended to reverse itself!) The second half-century of the Academy began just before the First World War, and again the Academy was called on to satisfy the technical needs of the armed forces. The growth of universities and the multiplication of industrial laboratories stimulated the increasing demand for scientists. As the United States emerged from international isolation, the Academy developed closer ties with its sister academies of other countries and acted as a centre of the integration of scattered and narrow specialisms. To symbolize the national significance of the Academy, the Carnegie Corporation of New York provided the funds for a monumental building in the capital. The centennial of the National Academy of Sciences was celebrated in the autumn of 1963. To mark the occasion many of the six hundred and fifty members of the Academy gathered in Washington with representatives of scientific bodies from other parts of the world. A number of foundations and corporations announced their generous intention to complete the House of the Academy that had been started forty years previously.

The President of the United States, the late John F. Kennedy, and twenty-three distinguished members of the Academy delivered memorable addresses in which the history of the universe, the nature of the matter, the determinants and evolution of life and the spirit of the scientific endeavour were described in a scholarly manner. Prof. I. I. Rabi summarized the proceedings by saying: "Day after day the mysteries of life were laid bare and, antecedent to life, the structure of matter, and indeed of the universe, were presented in dramatic and fascinating clarity. . . . The juxtaposition of topics did a very great deal to show the essential unity of scientific disciplines however different their techniques. . . . We listened to great wisdom".

The lectures were collected to form a book of considerable substance with adequate illustrations. The volume, even in its cheap paper-back version, is a worthy tribute to the occasion. The style of all the writers is clear and simple, and there has been no attempt to write down to the uninitiated in the popular style which nearly always leads to ambiguous statements, bad analogy and florid writing. These faults have been avoided absolutely.

*The Scientific Endeavour* divides naturally into five sections which are in the historic order of cosmic development. The history of the universe is considered in five chapters: "The Origin of the Elements", by William A. Fowler; "The History of Stars and Galaxies", by Jesse L. Greenstein; "The History of the Solar System", by Fred L. Whipple; "The Origins of the Continents, Oceans and

Atmosphere", by H. H. Hess; "The Origins of Life", by George Wald. The second section comprises the chapters on: "Symmetry and Conservation Laws", by Eugene P. Wigner; "Elementary Particles", by Geoffrey F. Chew; "The Structure of Nuclei", by Victor F. Weisskopf; "The Architecture of Molecules", by Linus Pauling; "The Organization of Living Matter", by George E. Palade. The third section deals with "The Determinants and Evolution of Life", which was introduced by Theodosius Dobzhansky and contains the lectures on "Genetic Determinants", by E. L. Tatum; "The Differentiation of Cells", by T. M. Sonneborn; "The Influence of the Environment", by G. Evelyn Hutchinson; "The Evolution of Living Systems", by Ernst Mayr; "The Physiological and Cultural Determinants of Behaviour", by Neal E. Miller. The fourth section was devoted to "The Scientific Endeavour" and consisted of lectures in "Communication and the Comprehension of Scientific Knowledge", by Robert Oppenheimer; "The Role of Science in Universities, Government and Industry: Science and Public Policy", by Jerome B. Wiesner; "Synthesis and Applications of Scientific Knowledge for Human Use", by J. B. Fiak; and "Science in the Satisfaction of Human Aspiration", by I. I. Rabi. The final section was devoted to a lecture by President John F. Kennedy on "A Century of Scientific Conquest". The book concludes with a bibliography of references for each of the lectures.

The eminence of each of the scientists who contributed to the occasion would indicate that each of the chapters is masterly both as an essay in science and in exposition. The whole book is a remarkable achievement, and the amount of consistently connected and developed information which it contains, particularly at so low a price, is remarkable. It should find many readers: the undergraduate, the graduate and the specialist in science. It should prove a means of obtaining a scholarly introduction to broad fields in the sciences.

W. L. SUMNER

## PLANT PHENOLICS

### Methods In Polyphenol Chemistry

Proceedings of the Plant Phenolics Group Symposium, Oxford, April 1963. Edited by J. B. Pridham. Pp. ix+146. (Oxford, London and New York: Pergamon Press, 1964.) 50s.

**A**PART from their intrinsic interest, deriving from the existence of a multitude of variations based on a relatively simple structure and their aesthetic interest as the source of a large proportion of the pigments which provide colour in plants, the plant phenolics have great importance, as a group, as an aid to plant classification by chemo-taxonomic techniques. Yet until quite recently the difficulties involved in their adequate separation and characterization were so great, and the methods so tedious, as to render their employment almost entirely impracticable.

Thus although among the most easily extractable and most visually characteristic of all plant compounds, it was only with the development of paper chromatography over the past fifteen or twenty years that their potential became exploitable. Particular interest therefore attaches to the symposium of the Plant Phenolics Group in April 1963, which is now published under the title *Methods in Polyphenol Chemistry*, and which was particularly concerned with the methods and techniques of analysis and characterization which has made this development possible.

Separation largely depends on chromatography, and as would be expected, a large part of the symposium was devoted to descriptions of the various techniques which have been found useful. These include contributions on paper chromatography by Bate-Smith, which contains a

most necessary plea for standardization wherever possible of solvents; on the use of thin-layer chromatography by Thaller; a particularly encouraging discussion of the use of the new polyamides by Horhammer; and a description of the application of gas-liquid chromatography by Norman and his colleagues. In addition there are two papers on the closely related subject of electrophoresis by Weigel and by Pridham, although it is pointed out that owing to its greater complexity this technique does not provide a substitute for chromatography, but may be a useful complementary tool for particular applications.

Just as chromatography has transformed the problem of separation, so spectroscopic methods have greatly simplified quantitative measurement and identification, and contributions at the symposium included papers by Harborne on the use of ultra-violet spectroscopy, with special attention to the relationship between structure and spectra and the use of the technique in the identification of new compounds; infra-red spectroscopy of flavonoids by Wagner; a description of preliminary attempts to make use of the sensitivity characteristic of spectrofluorimetry by Bridges; and a brief discussion on the basic principles of nuclear magnetic resonance spectroscopy by Abraham, with examples of its application to the determination of molecular structure in phenolics.

The final paper by Swain and Goldstein is concerned with the quantitative analysis of phenolic compounds, and is particularly notable for its cautionary approach, pointing out in respect to a number of possible techniques that while there is comparatively little difficulty in obtaining values of a sort, great care is needed to ensure that these are comparable and therefore meaningful, and the paper makes clear that a considerable amount of effort has been wasted as a result of failure to take this precaution.

Collectively the papers provide an excellent introduction to the range of techniques available for separation and analysis of phenolic compounds, though as a rule the scope of the particular techniques described is less well defined, and their limitations tend to be omitted. Individually the papers are well presented and highly readable, providing a high quota of information without being exhaustive or exhausting, and the volume can be recommended confidently to anyone interested in the subject. The book lacks an index, and even though the need for this is to some extent obviated by its shortness and division into clearly defined papers, this omission makes it unnecessarily difficult to look for information about particular compounds. This is unfortunate when one considers the very considerable amount of physical data relating to individual phenols which is contained in the various tables and figures.

P. A. THOMPSON

## OCEANOGRAPHY FOR ENGINEERS

### Oceanographical Engineering

By Prof. Robert L. Wiegel. (Prentice-Hall International Series in Theoretical and Applied Mechanics. Fluid Mechanics Series.) Pp. xi+532. (Englewood Cliffs, N.J., and London: Prentice-Hall, Inc., 1964.) 108s.

**I**T is realistic and progressive to maintain that hydraulic engineering should reach down river estuaries as far as low-water mark, and that oceanographic engineering should extend up the rivers as far as high-water mark. Prof. Wiegel, who holds the chair of civil engineering in the University of California at Berkeley, has such wide experience, and his new and detailed book *Oceanographical Engineering* can be recommended as a comprehensive guide especially to engineers engaged in coastal and harbour engineering. It gives much information that is essential to structural design but is more particularly outstanding in its description and appreciation of the factors that are likely to influence functional design and

the overall effect of the structure. Quite often the execution of a programme of improvement has created problems as severe as those it was conceived to solve, and differences of professional opinion about how problems should be tackled are often wide enough to demonstrate that basic understanding of the forces and motions involved is quite inadequate. It is too early for any complete theory, even of such an apparently elementary problem as the spacing, height and length of a system of groins, but there are partial and practical answers to many difficult questions, and the body of sound information is growing so rapidly that all designers are likely to gain useful guidance from it if they are prepared to face up to the unavoidably difficult analysis and reasoning. A large part of the book is devoted to waves, since they are important in almost every aspect of oceanographical engineering, and also because it is to this aspect of the subject that Prof. Wiegand's experience is most outstanding. He does not deal in detail with fouling organisms, submarine geology, underwater acoustics and sea-ice in which he has not specialized, or with corrosion and erosion of materials, or with measuring instruments for which the existing literature is already so large. But his 532 pages provide broad coverage and depth of information about most of the things that civil engineers want to know about the sea and which are not easy for them to enquire into.

The wave chapters review our knowledge of the theory of wind waves, much of it the outcome of recent work. They emphasize the need for further advanced theory and experiment because of the growing evidence we have of the importance of non-linear effects which could reasonably be neglected in the first approaches to the subject. Solitary and impulsively generated waves are also considered, with special reference to seismic seawaves, storm surges and harbour oscillations. These are followed by studies of the effect of beaches and structures on waves, including the effects of different kinds of breakwaters and resonant absorbers, of the nature of wave forces on different kinds of beaches and structures, and the longshore drifts and beach changes produced by them. There is a separate chapter on modern wave-forecasting procedures and their reliability, and a short note on tides and other changes in water-level and mean sea-level. Perhaps there should have been a more specific consideration of wave set-up—the inshore changes of sea-level which can be produced by oncoming swell without the agency of local wind. There is a chapter on the functional design of fixed and floating structures, piers, breakwaters, sea-walls, groins, underwater pipelines and sewer outfalls, and another on ship motion and on moorings.

Characteristics of ocean water, currents and mixing processes are described, but there is not much about ocean drilling, deep-sea prospecting, deep submergence vehicles and the increasing range of deep-sea technology, which is now referred to as oceanology.

The index is scarcely adequate, but it would be very difficult to refer to everything in a book so densely packed with information, tables, diagrams and references. It is quite an easy book to find one's way about in, and very rewarding.

G. E. R. DRACON

## PRINCIPLES OF HISTORICAL GEOLOGY

### Stratigraphy and Life History

By Prof. Marshall Kay and Prof. Edwin H. Colbert. Pp. 736. (New York and London: John Wiley and Sons, Inc., 1965.) 74s.

THE student reader of an introductory text on historical geology is faced with several difficulties additional to those of mastering new conceptions and a new vocabulary. In particular, the demands made on his geographical knowledge are considerable; and for this reason the most

useful elementary books are usually those describing the rocks of his homeland. This noteworthy volume by Prof. M. Kay and Prof. E. H. Colbert is concerned principally with the United States. Elsewhere, therefore, it is unlikely to be prescribed other than as collateral reading; but its very existence emphasizes the need for an equally well-illustrated introduction to the geology of Western Europe. Geology, like charity, should begin at home but not remain there.

In the usual fashion the book begins with a description of the rocks of the Pre-Cambrian era and then discusses the Phanerozoic systems one by one; but it is unique in that it essays to explain the principles of stratigraphical, petrographical and geochronological correlation by reference to the non-fossiliferous Pre-Cambrian formations, particularly the ore-bearing rocks of Michigan, Minnesota and Ontario. In fulfilling this difficult task it is remarkably successful. The principles of faunal correlation and faunal provinces are introduced with the description of Cambrian strata; and thereafter appropriate opportunities are taken to bring in various broad concepts on the tectonic control of sedimentation and similar matters. The palaeontology of the various systems, related in very general terms, dovetails with the accounts of the rocks and their palaeogeography; but there are three separate chapters on life in the Palaeozoic, Mesozoic and Cenozoic, and a fourth giving a systematic review of fossil organisms. The emphasis throughout is on the establishment of the principles which guide geological thinking. A chapter on continental drift is lucid reading but it is doubtful if one on the evolution of the crust in North America expresses its ideas sharply enough to be understood by the average undergraduate. A penultimate chapter on the origin of the Earth, by Dean B. McLaughlin, seems too remote to be relevant.

When the authors' writing touches on geochemistry it is much less felicitous and slips are frequent. On pp. 66–69 we are told that "there are two forms of isotopes of uranium", that  $^{238}\text{Pb}$  is primary lead, and that  $^{40}\text{K}$  forms 1 per cent of natural potassium (although the accompanying diagram gives the correct value of 0.012 per cent); and it is wrongly implied that an age determination can be derived from the ratio  $^{235}\text{U} : ^{238}\text{U}$ . On pp. 82–83 it is not made clear that the figure of 2,700 m.y. for the oldest rocks relates solely to North America—there are much older formations in Russia and southern Africa; or that the age of 1,700 m.y. given for the Gunflint and Biwabik iron formations is their metamorphic date—the date of sedimentation is much older, as shown on p. 49. Similarly on p. 594 it is said that "there are two isotopes of carbon having atomic weights of 14 and 12: the latter is common carbon". On p. 91 the uraniferous hydrocarbon in the Cambrian shales of Sweden is wrongly referred to as pitchblende; and a reader could pardonably gain the impression that dolomites do not appear before the Silurian (all earlier references are to limestone) and that all dolomites are penecontemporaneous. Students should not be encouraged to use the old term Proterozoic for the Pre-Cambrian in view of potential confusion with Proterozoic. It does not appear in the American Geological Institute's dictionary.

In its wealth of illustrations, this text-book is the most lavish of its kind yet produced. A large page size (30 cm × 24 cm) has permitted about half the total space to be occupied by photographs and diagrams, accompanied by lengthy explanations; but only a persistent reader will finally locate a description of the frontispiece photograph on p. 436, and of the dust jacket on p. 176. A coloured geological map of North America is printed inside the jacket. Reproductions of dioramas of palaeontological habitat groups, mostly from exhibits in American museums, present a vivid representation of life through the ages. Some other diagrams of fossils (particularly of microfossils) could have been improved by the addition of a scale.

O. F. DAVIDSON

### The Theory of Order-Disorder In Alloys

By M. A. Krivoglaз and A. Smirnov. Pp. x+427. (London: Macdonald and Co. (Publishers), Ltd., 1964.) 90s.

IN an ordinary metallic solid solution of, say, a two-component system, the two species of atoms are arranged at random on the points of the crystal lattice, and at a composition  $AB$ , for example, any particular lattice point may be occupied by either  $A$  or  $B$  atoms. In certain systems, however, below a critical temperature, segregation of one kind of atom to a certain set of lattice points can occur, leaving the other kind to the remaining positions. This phenomenon is known as 'ordering'. The possibility of ordering had been suggested by Tammann in 1919, and was confirmed by the X-ray work of Bain in 1923. Since that time many metallic systems have been discovered to have this property at certain simple ratios of  $A$  to  $B$ , the best-known examples occurring at compositions  $AB$  and  $A_2B$ , such as  $Cu_3Au$  and  $Ag_3Zn$ . Clearly such a modification of the structure of the alloy as the temperature falls is expected to influence in turn many of the physical and mechanical properties, and a considerable theoretical structure has been erected to relate the observed changes in properties to changes in the models of the electronic structure.

The present volume is a translation from the Russian, and the approach is largely theoretical. It consists of eight chapters. The first chapter is a general review of the properties of ordered alloys, and the second, third and fourth deal with the thermodynamic and statistical theories of ordering, and with the theory of diffusion. A discussion of the effect of ordering on the behaviour of the valence electrons appears in chapter five, and the effect of ordering on wave-motion in chapter six. Chapters seven and eight cover the theory of residual resistivity and the magnetic, galvanomagnetic, optical and mechanical properties of metals and alloys.

The book is aimed at graduate and post-graduate workers and is a fairly comprehensive treatise on the theoretical aspects of ordering. However, there are a number of points of criticism. The treatment is excessively formal, and the explanation of the relation between the mathematical and physical models is disappointing. The first chapter of ninety or so pages is well illustrated with eighty-six figures, but the remaining three hundred pages have only twenty-eight illustrations between them. It is pleasant to have many references to Russian work in the text, but the overall balance of the book suffers. For example, in the chapter on the theory of the residual resistivity of alloys the names of Mott and Friedel do not appear. The book has three hundred and thirty-seven references, but since it was published in Russian in 1958 the most recent reference is 1957. In the copy sent to me for review the quality of the printing and the pages was somewhat uneven. There is no index, and in view of the price one can make only a cautious recommendation.

J. A. CATERALL

### Ultrasonic Cutting

By L. D. Rozenberg, V. F. Kazantsev, L. O. Makarov and D. F. Yakhimovich. Translated from the Russian by J. E. S. Bradley. Pp. xi+142. (New York: Consultants Bureau, 1964.) 17.50 dollars.

THIS carefully translated text is based primarily on the experience of the authors in the Ultrasonic Laboratory at the Acoustics Institute of the Academy of Sciences of the U.S.S.R., and in the Special Designs Office of the Moscow City Economic Council. The authors have, however, attempted to make due note of work done elsewhere—both inside and outside the U.S.S.R.—and the inclusion of more than 220 literature references is one result of this.

Since this book should be just as useful in creating interest in, and potential users for, this technique, as in providing a reference text for those already expert, it may be as well to give a brief reminder of what ultrasonic

cutting is. It is a manufacturing process that has developed over the past twenty years to facilitate the cutting of, or drilling of holes in, materials normally too brittle for working by conventional methods. A slurry containing extremely hard abrasive particles (for example, 'Carborundum' or boron carbide) is fed to the working position, where an acoustically designed tool of relatively soft material vibrates at ultrasonic frequency, hammering down on the trapped particles. In this way an extremely rapid succession of intense 'micro-blows' is imparted to the working surface which thus erodes away, leaving a cavity which reflects the shape of the acoustic tool. Accordingly, and depending on the manner in which the tool is vibrated (for torsional vibrations have as much usefulness as longitudinal vibrations), it is possible to produce round holes, non-circular holes, twisted holes, slots, curved holes, disks and internal and external screw threads, among other forms. Versatility is limited only by the nature of the workpiece material, which must be brittle.

The text covers basic principles as well as practical development. The first chapter discusses elastic wave propagation and vibration for various media, both solid and fluid. Subsequent chapters show how these concepts lead to a detailed understanding of ultrasonic machining, so that—making use of piezo-electric or magnetostrictive excitation—the acoustic tool head may be logically designed to achieve the desired effect. Discussion thereafter widens to deal with different types of ultrasonic machine tool, and indeed with the whole technology of the process.

The book is remarkably readable: the mathematical analysis employed in the early chapters is a digestible minimum and is well presented. Apart from the numerous references already mentioned, the text is finally supported by 31 well-chosen tables of numerical data, and 155 clear illustrations.

### Contributions to Sensory Physiology

Vol. 1. Edited by William D. Neff. Pp. x+274. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1965.) 60s.

THIS is the first volume in a new series of publications which has two main objectives, to bring together reports of current research on sensory physiology, and to enable individual research workers to present some particular theory of the physiological basis of sensation. They are definitely not intended to be review articles.

Of the five articles which it contains, three are concerned with vestibular function. The first is a study of the organ of Corti at a cellular level, another concerns the functional anatomy of the ciliated end organs of the labyrinth and lateral line and the third is a psychophysiological study of vestibular responses. If the editors continue to bring together articles like these, which are not normally found in the same volume, the series will certainly fulfil a useful function.

The remaining two articles are on vision and are of particular interest from the comparative point of view as one gives an account of work, some unpublished, on the vision of various primates, while the second is a translation from the French of a paper by Piéron on vision in intermittent light. It is a sad fact, but nevertheless true, that many English-speaking biologists have little time to digest the details of longer papers written in other languages. The publication of translations of this type could do a great deal to help in the dissemination of results that otherwise might not be read in the detail they deserve.

The whole volume is well bound, and has a good reference list and author and subject indexes. It is only unfortunate that the price is so high for it adds to the ever-increasing burden that libraries must bear in subsidizing the costly production of volumes of this type.

G. M. HUGHES

OBSERVATIONS OF RADIO GALAXIES WITH THE  
ONE-MILE TELESCOPE AT CAMBRIDGE

By PROF. M. RYLE, F.R.S., B. ELSMORE and ANN C. NEVILLE

Mullard Radio Astronomy Observatory, Cavendish Laboratory, Cambridge

ON July 8, Lord Bowden and other distinguished guests visited the Mullard Radio Astronomy Observatory, Cambridge, to inspect the new, large radio telescope<sup>1</sup> which has recently come into use. This instrument, which was constructed with the aid of a grant from the Science Research Council, makes use of an advanced form of aerial synthesis to provide a resolution and sensitivity considerably greater than have been achieved hitherto.

The telescope was designed primarily to further our understanding of the physical processes occurring in radio sources of different types, both galactic and extragalactic. In each case one of the chief requirements is a detailed knowledge of the structure for different wave-lengths and polarizations. Although the large baseline interferometers at Jodrell Bank<sup>2</sup> have set lower limits on the surface brightness occurring in many sources, they have not provided much information on their shape. More detailed interferometric observations, but with less-extensive baselines, have been made at the California Institute of Technology<sup>3</sup> and the results have been interpreted in terms of various simple models of the brightness distribution; these models may not, however, be unique, and information has not been obtained for more complex sources.

From what is already known about the intrinsic radio luminosities of radio galaxies and quasars, it is clear that

an investigation of the numbers of sources occurring in different ranges of flux density, and the examination of the spectra and other features of sources of different flux density, may allow powerful tests of different cosmological models. The present observations<sup>4-6</sup> have already imposed important restrictions on the possible models, and these restrictions should be increased if the observations can be extended to weaker sources; such an extension requires an instrument having both greater angular resolution and greater sensitivity.

The new telescope has been designed with these needs in mind. In the earlier large instruments at Cambridge, a long, thin aerial has been used in conjunction with a smaller movable one to carry out a one-dimensional synthesis. In the new telescope, the method is extended to two-dimensional synthesis using relatively small circular elements the spacing and orientation of which are varied to include all the relative positions present in the large equivalent aerial. Use is made of the rotation of the Earth to alter the projected position angle of an east-west axis on the sky; by using aerial elements capable of tracking a given point in the sky for 12 h all the information appropriate to an elliptical ring of a large equivalent instrument is obtained<sup>1</sup>. By repeating 12-h runs at each of a number of east-west separations, it is then possible to

Fig. 1. The three 60-ft. paraboloids of the new telescope. The moving aerial and rails can be seen in the foreground.

Fig. 2. Curves showing as a function of wave-length: (a) the variation in flux density of a typical radio galaxy; (b) the total system noise of a typical installation using low-noise amplifiers; and (c) the ratio of (a) and (b).

build up an equivalent elliptical aerial the major and minor axes of which are  $D$  and  $D \sin \delta$ , where  $D$  is the maximum separation of the aerial elements and  $\delta$  is the declination of the area of sky under observation. A maximum separation ( $D$ ) of about 1 mile (1,550 m) can be used in the new telescope.

Owing to the high cost of the stable rail foundations, two fixed paraboloids are used in conjunction with a movable one on 0.5 mile of rail track; this arrangement permits two different separations to be recorded simultaneously and halves the observing time. The use of an even shorter rail track and a larger number of fixed elements would have reduced the observing time still further but would have resulted in an increased cost.

The three elements may be seen in Fig. 1. Each is an equatorially mounted paraboloid 60 ft. in diameter. The instrument is being used to observe simultaneously at two wave-lengths, 74 and 21.3 cm, at which the final beam-widths are 80 and 23 sec arc respectively.

It is interesting to compare the signal-to-noise ratio achieved with this system, with those of more conventional instruments of the same resolution when used to observe a given area of sky in a given total time. If  $d$  is the diameter of each of the aerial elements and  $D$  is the maximum separation, it can be shown<sup>1</sup> that the signal to noise in the final map is equivalent to that of an instrument with a collecting area of approximately  $3d \times D$ , or  $10^6$  sq. ft. In addition, the ability to use wave-lengths considerably greater than those which would have to be used in a feasible paraboloid to obtain the same resolution confers a further improvement in the relative sensitivity. In Fig. 2 curves are shown of the relative flux density of a typical radio source at different wave-lengths together with typical values of the overall system noise (receiver noise and radiation from the ground and sky). It can be seen that the ratio of these two curves shows a well-defined maximum in the neighbourhood of 50 cm. If, for example, a resolution of 23 sec arc were to be achieved by the use of a 200-ft. paraboloid operating

on a wave-length of 8 mm, the relative sensitivity would fall below that of the new instrument operating at  $\lambda = 21$  cm by a factor of about 300.

Apart from the question of the engineering feasibility of constructing a paraboloid with sufficient accuracy to provide a resolution better than 1' arc, it is therefore clear that if such an instrument were to provide maps having a comparable signal to noise, then the observing rate would have to be very much slower than that of the new telescope.

The aerials may be controlled individually but, normally, they are all operated from the Central Control Room shown in Fig. 3. This building also contains the receivers, digital converters and paper-tape punches on which the signals are recorded. When observations are made away from the meridian, large path differences to the different elements occur and it is necessary to introduce a path correction which varies continuously as the observations proceed. This correction and the control of the punches and telescope tracking motors are made automatically by means of a control tape previously prepared in the computer.

During the first seven months, the instrument has been engaged in three main observing programmes:

### (1) Accurate Positions

In order to make full use of the resolution available at  $\lambda = 21$  cm, the relative positions of the three instruments must be established with an accuracy better than  $\sim 0.5$  cm.

Attempts have been made to determine the necessary quantities (a) by observing small-diameter radio sources associated with stellar objects the positions of which have been accurately measured<sup>10,11</sup> and (b) by direct survey methods. The former method has been used by Adgie<sup>11</sup> and, as he points out, it suffers from the rather small number of sources for which the identity of optical and radio positions can be assumed; most of the sources also lie in a limited range of declination. For the second method we are indebted to the Ministry of Public Building and Works for the final survey of the instrument with an accuracy believed to be 1 in  $10^6$  and 0.5 sec arc.

A comparison of the two methods has revealed discrepancies greater than the uncertainty expected from either of the survey methods.

Although the cause of this discrepancy has not yet been discovered, it is possible to use the present results to determine the positions of sources having  $S_{21} > 2.5 \cdot 10^{-26}$  Wm<sup>-2</sup> (c/s)<sup>-1</sup> with an accuracy of  $\pm 3$  sec arc in  $\alpha$  and  $\pm (2.5 \cos \delta)$  sec arc in declination.

Fig. 3. The control desk and part of the receiving system.

Some 50 sources have been observed, about half being apparent point sources. The positions of a number have been examined on the prints of the 48" Sky Survey and some possible new identifications have been noted. These include blue stellar objects close to the positions of the following sources: 3C 270-1, 3C 277-1, 3C 309-1 and 3C 454.

## (2) Source Structure

When observing intense sources, the angular size of which is considerably less than the primary beam of the individual aerials, it is unnecessary to make observations with all separations of the aerial elements. Instead, a relatively small number of positions of the moving aerial along the full length of the rail track can be used to synthesize a grating instrument. This method was employed in the observation of the intense sources in Cygnus and Cassiopeia already reported<sup>12</sup>. Some of the sources investigated have been observed previously by Moffet and Maltby<sup>3</sup>, who fitted simple source models to their observed amplitude-spacing curves. In several cases the distribution of radio brightness has been found to be more complex, while in others the sources have not previously been observed with sufficient resolution to show the detail now seen.

The results are presented automatically as contours on a curve plotter attached to the *Edsac II* computer.

Fig. 4. 3C 47. The optical quasi-stellar object is marked by a cross

Fig. 5. 3C 103. The central of the three objects shown is probably a star with  $m_{\text{vis}} = 16$ . Two diffuse red objects ( $m_{\text{vis}} = 18-19$ ) are also visible

Fig. 6. 3C 29 41. The two 15 15" galaxies in a common halo are shown

Observations have been made on both 74 and 21 cm; the maps obtained for some of the sources on a wave-length of 21 cm are shown in Figs. 4-7. In order to simplify the examination of the structure of the sources, the scales of all the maps are such that the beam appears circular; the scale of the maps is therefore the same in right ascension, but varies as  $\sin \delta$  in declination.

(a) 3C 47. This source was one of the original group of quasars<sup>13</sup>. The new observations (Fig. 4) show that it consists of two components having flux densities in the ratio 1.8 : 1. The components have an angular separation of 62 sec arc and are disposed nearly symmetrically either side of the optical object which lies about 8 sec arc north of the line joining them. The more intense component is just resolved with an angular extent of  $\sim 10$  sec arc in R.A.; the weaker component cannot be resolved, but could be of the same angular size. The interferometric observations of Anderson *et al.*<sup>14</sup> and the absence of interplanetary scintillations<sup>15</sup> have shown that there is little structure as small as 2 sec arc.

The optical object has a red-shift  $\Delta\lambda/\lambda = 0.452$  (ref. 13), and the observed angular separation of the two components corresponds to a physical separation of 200-300 kpc depending on the cosmological model adopted. It is therefore physically one of the largest radio sources known, with a component separation some three times that of Cygnus A; its radio luminosity is nearly the same as that of Cygnus A.

This result is important in relation to theories of quasars and radio galaxies, since, even if the two components are supposed to be ejected at speeds close to that of light, and in a line perpendicular to the line of sight, the radio source must be at least  $3 \times 10^6$  years old; a life in excess of  $10^6$  years seems more likely. The presence of intense ultra-violet emission from a stellar object associated with such an old source indicates either that there is a continuing source of energy for the ultra-violet source which does not give rise to intense radio emission, or that a second release of energy can occur in such objects.

The large physical dimensions of the two emitting regions (7-35 kpc) also require a total energy in the form of fast particles and magnetic field, which is comparable with that of Cygnus A ( $\sim 10^{44}$  ergs). As discussed by Fowler<sup>16</sup>, the relatively short life-time which has been associated with quasars only requires sources of energy of  $10^{43}$ - $10^{44}$  ergs; the association of a quasi-stellar optical object with a radio source having energy requirements some 100-1,000 times larger may place greater emphasis on those mechanisms of energy release in quasars which are capable of supplying this greater energy.

(b) 3C 103. This source (Fig. 5) consists of two components separated by 88 sec arc, each having an angular

Fig. 7. 3C 452. The 16<sup>m</sup> galaxy suggested as an identification (refs 18, 19) is shown at  $\alpha = 22^{\text{h}} 43^{\text{m}} 32^{\text{s}}$ . This galaxy has a red-shift  $\Delta\lambda/\lambda = 0.062$ , implying a separation between the outer peaks of 280 kpc.

diameter  $< 10$  sec arc; a faint bridge joins the two components. The south following component has a flux density some 1.9 times greater than the other. No associated optical object has previously been suggested, and the low galactic latitude ( $b_{\text{II}} = 7^\circ$ ) may involve considerable obscuration; some possible objects are marked in Fig. 5.

(c) 4C 29.41. This is a source from the 4C catalogue<sup>17</sup>. Its flux density at 21 cm is  $1.8 \times 10^{-26} \text{ Wm}^{-2} (\text{c/s})^{-1}$  and it consists of an extended or double major component, separated from a second, unresolved component, by 50 sec arc (Fig. 6). Two 15<sup>m</sup> elliptical galaxies in a common halo are probably associated with the radio source.

Fig. 8. Part of the first deep survey at  $\lambda = 74$  cm obtained with the new instrument; the figure covers an area of about 1 sq. degree. The source near the centre has a flux density about 1/25th that of the weakest sources in the 4C catalogue (ref. 17).

(d) 3C 452. The contour map is shown in Fig. 7 and reveals a remarkable ridge of emission 4 min arc in length and 20 sec arc in width; it also shows an intense and elongated source at either end of the ridge, neither of which is completely resolved in declination.

The position of a galaxy which has been suggested by Dewhurst<sup>18</sup> and Matthews<sup>19</sup> as the identification is shown in Fig. 7.

### (3) Deep Survey

A test survey has been made using the instrument to synthesize a full 1-mile aperture in order to provide a detailed map of an area of sky which is some  $3^\circ$  in diameter at 74 cm and 50 min arc diameter at 21 cm. The amplifiers used in these observations were only of moderately low noise-level ( $T_R = 450^\circ$  at 74 cm and  $400^\circ$  at 21 cm), yet nevertheless extremely faint sources can be distinguished. Part of the 74-cm map (of area approximately 1 sq. degree) is shown in Fig. 8. The more intense component of the double source in the lower right-hand corner has a flux density  $S_{74} = 0.17 \times 10^{-26} \text{ Wm}^{-2} (\text{c/s})^{-1}$  and the source near the centre of the map has  $S_{74} = 0.04 \times 10^{-26} \text{ Wm}^{-2} (\text{c/s})^{-1}$ .

We thank Dr. S. Kenderdine who was responsible for the reduction of the deep survey observations, Miss Judy Bailey for help in the programming, E. A. Parker for permission to use the results of his search for optical identifications before publication, and Prof. M. V. Wilkes for the use of the *Edsac II* and *Titan* computers.

## PROFESSIONAL OBSOLESCENCE AND THIS RAPIDLY EXPANDING TECHNOLOGICAL ERA

By DR. D. C. SAYLES

Propulsion Laboratory, Directorate of Research and Development, U.S. Army Missile Command,  
Redstone Arsenal, Alabama

IF you have graduated prior to 1959, there is a strong probability that you are becoming 'technically obsolescent'. Technical obsolescence means this: a competent technical person with an excellent formal education finds himself, after some years of practice, unable to discharge his technical responsibilities effectively. Young scientists, entering employment, have only a 'breather' before they must plan to refresh their knowledge and techniques, because at the present rate of research discovery, their training will be adequate for about five years. But professional obsolescence can deliver a real knockout blow to older scientists if they do not follow new developments and ideas; they may reach a dead-end in their careers by the time they are forty-five years of age.

The problem can be summarized as follows. Graduates of ten years ago have to spend a minimum of 10 per cent of their time acquiring technical knowledge beyond their original academic training if they hope to compete in value with more recent graduates. This statement is, of necessity, predicated on the assumption that they have retained most or all of their previous training. However, if the loss of unused knowledge is 10 per cent per annum, and the advance in new knowledge is also 10 per cent, scientists must then grow in knowledge at a rate of 20 per cent per annum to remain of equal value to their employers. In the past, scientific meetings, conferences and seminars were relied on as the means of keeping scientists informed about new advancements, but this is no longer adequate.

### Technical Obsolescence not a New Problem

Technical obsolescence is a problem, a very serious problem, but it can scarcely be considered a new one. It has always been hazardous for a scientist to permit himself to operate indefinitely on the training and education which was acquired formally. The modern problem is complicated by the fact that scientists can no longer update their technical knowledge without assistance from many sources. Help is needed. Basically, this is because, when technical obsolescence does occur, it appears at the foundations of the scientist's training rather than in the day-to-day problems which he encounters. The rapid accumulation of new technology, especially in advanced engineering and in the various phases of weapon design, space and other aspects of technical power politics, makes technical obsolescence and updating of technical skills a very serious matter.

The late Eger Murphree listed the threat of technical obsolescence as "at least a hundred billion dollar problem". The American Chemical Society has estimated that 23 per cent of all the research in chemistry throughout the entire history of the world was conducted over a four-year period between 1957 and 1961. Similar comments can be made about the other physical sciences. Small wonder, then, that there is a desperate need for updating the technical backgrounds of our scientists.

### Definition of a Professional

A professional is paid for making value judgments. These judgments affect life, property and money. The

better the quality of these judgments, the greater the remuneration should be. The compensation should also vary directly with the magnitude of the difficulty involved in making the judgment.

Some examples of professional personnel are: traditionally, the medical doctor and the lawyer; and, more recently, the aircraft pilot and the personnel manager. It would, therefore, appear that this designation of 'professional' is somewhat arbitrary; however, they do have one aspect in common, that is, they are required to make judgments. By this definition, the scientist would also be classified as a true professional. He must acquire information on which to base a judgment, and then reach a decision. This he does since he must decide which way a research programme should be oriented; what experimentation should be conducted; evaluate the results; plan new approaches, and report to management.

### Pre-requisites for Practising a Profession

Now what does it take to prepare a professional to perform his functions? In order to practise his profession, a scientist must learn the rudiments of a particular science and its techniques of practice. After graduation, and during the period that he is practising his profession, it is necessary for him to keep informed of the changes in knowledge relative to the practice of his profession.

Since the making of a judgment is a step, regardless of how small, into uncharted territory, and not a rehearsal of already known ideas or fact, the professional scientist must have at his finger-tips the latest knowledge and facts concerning the area where the judgment is to be made. This, in conjunction with previously acquired knowledge, will only then provide the foundation for a valid judgment.

### Stimulation of the Professional Scientist

The scientist must be stimulated in order to provide an essential growth atmosphere in which his curiosity and thirst for knowledge are continuously nourished and his sense of values maintained. A yardstick must be provided so that he can periodically measure the degree to which he is falling behind. This can very aptly be illustrated by an over-simplified analogy. A person fluent in French will have a difficult time maintaining this linguistic dexterity in an English-speaking environment. In fact, in such an environment, there exists no challenge or yardstick for gauging whether his fluency in French has slipped to any degree. Motivated by his deep love for the language, he can resort to the use of language records and other teaching aids in an effort to retain or augment his knowledge of the language. Nevertheless, he is destined to forget, and forget he will, for two reasons: nobody challenges him to demonstrate what he has remembered, and as he associates with the people in his immediate vicinity, he is not provided with a means which enables him to gauge the degree to which he is becoming obsolete.

Now, suppose that this individual elects to aspire to a higher level of recognition, and suppose that this level requires that he learn German. If the rewards for such recognition appear of sufficient significance to him, he will

have to modify his sense of values, and seek such recognition. In doing this, he is confronted with a more complicated situation since he now runs the risk of forgetting his skill in French at an even more rapid rate. This risk is very real, and has been labelled the 'risk of management', since the risk of accelerating technical obsolescence occurs in the pursuit of higher management responsibilities.

### Types of Professional Obsolescence

(1) *Keeping up with the literature.* There are two different types of professional obsolescence. At one end of the spectrum there is an obsolescence resulting from an inability to keep abreast of the present literature in a particular scientific area. That is, an inability to keep up with the newly obtained results and changing postulates. In this age of the so-called publication explosion, many insist that such an effort is, at best, a losing battle, and it must be conceded that, in these busy times, the battle requires great personal sacrifice in time and effort. Some claim that it is physically and intellectually impossible to keep abreast in any particular scientific field.

Keeping up with the present scientific literature is a 'must' in order to minimize the risk of individual obsolescence. In its essentials, the problem is how to ensure that the individual's fixed amount of reading time is used on that particular selection from the available present flow of new information which is optimum for him. Selectivity is the keynote, as it has always been, and its crucial importance increases with the steady rise in volume of output available.

Proliferation of the literature, at the present time, appears to be proceeding faster than the rate of improving the know-how to cope with it. This means that unremitting effort is required from the scientist, and initiative is required to achieve a relative gain and not decline in the mastery of a reading programme.

(2) *Preventing erosion of the scientist's basic discipline.* At the other end of the spectrum is the failure to keep up with the fundamental structure of the scientist's basic discipline. In this situation, the job of keeping up is really much easier. In fact, the ready availability of well-written text-books, review articles, symposia, etc., places this achievement within the grasp of almost every scientist. Publishers and outstanding scientific writers are aware of this deficiency, and an increasing number of text-books specifically designed to teach concepts are now appearing. From this point of view, this latter kind of technical obsolescence warrants attention because it exists when, in fact, it should be very rare.

### Examples of Advances In Modern Technology

Since the Second World War, the rising level of expenditure on research by the Federal Government and industry (from 5.2 billion\* dollars in 1953 to an estimated 19 billion dollars in 1965) has produced a host of major new technological advances which will have a profound influence on the future of all scientists and non-scientists. Technological obsolescence is not restricted to a particular scientific discipline. The defence-space programmes have been the sources of a large number of new advances which overlap many scientific disciplines. This can be most appropriately illustrated by the impact these advances have had on the steel industry. The competitive pressures for aluminium, plastics and reinforced concrete, combined with the domestic and foreign market pressures in this industry, have rendered economically obsolete much of the industry's present steel-making facilities. These pressures are forcing companies to install new facilities that embody an entirely new steel-making technology. As a consequence, the scientists in this industry are confronted with the need of acquiring newer skills required for these more modern methods of production.

\* 'Billion' mean a million millions in Britain and elsewhere, but a tenth of that (a thousand millions) in the United States and some other countries.

Another example can be garnered from the field of electronics. This field has rapidly outgrown its initial role in radio, television and communications. It has not only developed into a basic scientific discipline in its own right, but has also broad potential application in virtually all areas of scientific endeavour. As greater knowledge and understanding are attained, it is becoming increasingly possible to accomplish many tasks by electronic techniques rather than by mechanical or electromechanical devices. A list of such inroads would include these significant accomplishments: electronic telephone switchboards; electrostatic printing; electrochemical machining; electrical discharge machining; numerically controlled metal-working; computerized typesetting; photocomposition printing.

Another example, and one that is of particular interest to this group, can be labelled as 'engineered materials'. The traditional approach to materials research was segmented into numerous specialized areas of interest, such as ferrous metals, non-ferrous metals, plastics, rubber, ceramics, etc. This concept is rapidly being superseded by research based on the concept that the same fundamental principles underlie the behaviour of all materials. With a more thorough comprehension of the underlying relationship between the basic structure of materials and their physical properties, the synthesis of 'engineered' materials, such as propellants, which have properties that are best suited for a particular application becomes a reality. The more important recent outgrowths of this new science of engineered materials include transistors, tunnel diodes, masers, lasers, piezoelectric devices, etc.

The final example, which warrants some attention, is numerical control. This is regarded as a most significant development in manufacturing technology and is comparable with Henry Ford's development of the assembly line. It brings to the field of small-volume production many of the manufacturing economies which are at present inherent only in highly automated production systems.

Although numerical control has attained its highest state of development in the machine tool industry, this new concept has many potential applications. These include the inspection of finished products, metal flame-cutting, wiring and assembly of electronic printed circuit boards, and the preparation of engineering drawings.

### Programmes for bringing Scientists up to Date

The fight to keep up with fast-moving scientific developments requires the resources of the individual, industry, professional societies, government and academic institutions. Some employee education programmes exist, but are fairly new and still in the trial stages. Their effectiveness is, therefore, difficult to assess.

(1) *Projected educational changes in night schools.* Despite the changes that are projected for high schools and colleges during the coming decade, the greatest impact will probably be felt in adult night school education. Although business and Government will be forced to increase their re-training activities for their scientific personnel, it is most probable that a substantial portion of the re-training and bringing up to date will have to be provided in adult night-time programmes. Night school is expected to become an accepted part of the weekly activities of a large segment of a country's technical force. The growing need for adult night-school education poses several serious problems. This will be particularly so for the educational systems in urban areas because it will be here that the impact of obsolescence will be more deeply felt. Not only will school systems be faced with the challenges of providing adequate facilities and qualified educators to meet the expanding needs of the night school programmes, but also these challenges will be compounded further with the more difficult problem of trying to provide training in entirely new scientific fields

which are not well defined and which are in a constant state of flux.

(2) *Projected changes in college training.* I need scarcely point out the serious deficit of college facilities for handling the educational needs because of the exploding population. The offering of refresher courses to the technically trained would further tax the facilities of these institutions. In addition, the evening courses which are at present being offered are generally a portion of degree-oriented programmes, and are, therefore, not readily available, nor geared for, those interested only in furthering their knowledge in a particular field. Colleges and universities, especially those in urban areas, will thus be confronted with the necessity of markedly increasing the number of non-degree educational programmes which are offered. Because of the lack of adequate facilities, they will find it necessary to develop new relationships with the local schools so that college-level programmes can be provided through existing school systems. The acquisition of an adequate professorial staff who are fluently conversant with the newer and constantly changing scientific disciplines is going to be a problem of major magnitude.

Another approach would consist of developing intensive courses from its undergraduate and graduate curricula which would then be taught by regular faculty members during the summer session 'in-plant'.

(3) *Projected changes in the activities of professional societies.* The role of professional societies in updating the technical training of their members has been frequently debated. The American Medical Association has pioneered one approach. Various practising groups in the medical profession are required to hold frequent clinical conferences and programmes designed to keep their members abreast of new developments. For example, the American Academy of General Practice with 27,000 members (about one-third of the general medical practitioners) requires its active members to engage in and complete 150 hours of postgraduate education acceptable to, and outlined by, its Commission on Education in each three-year period. If a participant fails to comply, active membership is not renewed. Similarly, the American Institute of Chemists has recently introduced the regulative principle of "Accreditation of Scientific Modernism". The intention is to stimulate the individual chemist or chemical engineer to protect himself against the outdating of his technical skills. For accreditation, the individual's recent scientific updating efforts are reviewed by local examining boards, which then recommend whether the candidate should be accredited.

Further, considerable modification of the methods for conducting the national meetings of the professional societies is a necessity to cope with the changing times. Present emphasis at these meetings is on the presentation of detailed research discoveries in highly specialized areas of a particular science. More appropriately, with the secondary goal of providing the opportunity of bringing those attending up to date, some summary or review papers which discuss the more recent developments should be liberally interspersed among these fundamental papers.

(4) *Efforts by industry and Government to bring their scientists up to date.* Certain industrial organizations have already taken several important steps in supplying the tools which are needed to ensure that their scientists can keep up to date. The plans for such endeavours are in the form of advanced degree programmes, including educational leaves of absence for its scientific employees, and co-operative plans with universities where facilities and staff are made available for providing advanced and refresher courses on the job.

Most of these employee educational programmes are new, and are still in the trial stages, and therefore their success is difficult to assess. Consequently, it is not possible to estimate the number of scientists who are already engaged in updating their technical backgrounds.

What little experience is available indicates that many professional personnel have not taken the matter of personal obsolescence seriously as yet.

Some comments about the more important stimuli for updating follow.

### Tuition Payment Plans

Payment of part or all of the tuition costs for employees seeking advanced degrees has existed within the United States for a considerable time. These plans have been especially motivated in providing the incentives for advanced study. A limited survey, conducted by the Outboard Marine Corporation in 1961, suggests that these programmes are growing in popularity with employers but not necessarily with employees. According to the survey, an average of only 6 per cent of the eligible employees have seen fit to take advantage of the tuition-paid educational plan.

### 'In-plant' Programmes

Additional 'in-plant' educational opportunities for technical employees are needed. The lecturers can be recruited from either within or outside the organization. These lectures should comprise survey courses provided by qualified university staff members or by senior employees of the organization's own scientific staff who can present such courses to their younger associates and to members of other departments. Employees should have full-time assignments to attend these courses in company time.

### Newer Tools for fighting Technical Obsolescence

There are three principal kinds of newer tools, namely, computers, copying and recording devices, and rapid communication systems that can be used in meeting the educational crisis facing the country.

The use of the computer and associated technology will make the literature more readily accessible to each scientist. This mechanical slave can accomplish the tasks of extracting, assembling and coarsely organizing whatever information is in the literature stockpile which corresponds to the questions which are posed. For the start-up of such a new method, however, large tasks are involved, such as the organization of the total information accumulation into suitable fashion, and the provision of pre-tested operational techniques.

There is little doubt that the new schemes should provide an exceptional service in the treatment of facts, such as molecular structure, mechanical properties, etc., which appear in the literature. The computers can manipulate these results to effect correlations among these, and this would be extremely difficult and tedious without machine aid. However, when it involves literature components which are primarily interpretative, theoretical or speculative rationalizations, less satisfactory results will have to be acceptable. The reasons are rooted in the difficulties of precise indexing of the less-specific and less-precise pieces of information. Conceptual themes weave in and through large aggregates of facts, and are, consequently, difficult to index for effective mechanical manipulation by the mechanical rigour which computer programmes demand.

The adoption of computerized information storage and retrieval techniques will interfere with the ability to browse. Browsing is a desirable capability, and is useful and essential, especially to those engaged in truly fundamental research.

Newer communication developments, such as television, tele-lecture, 'blackboard by wire' and conference calls, are additional techniques which, when used in combination and in conjunction with present systems, can be projected to alter greatly teaching methods.

## OBITUARIES

## Sir John Russell, O.B.E., F.R.S.

SIR JOHN RUSSELL, director of Rothamsted Experimental Station during 1912-43, and for more than half a century a dominant figure in world agriculture, died at Goring on July 12, 1965. He survived Lady Russell, who constantly supported him through an exceptionally long and active career, by only three months, and he finished his last book, a history of agricultural research in Great Britain, only a few weeks before his death.

Edward John Russell was born in 1872 at Frampton, Gloucestershire, the son of a school teacher who later became a Unitarian minister. His family was unconnected with either agriculture or science; but his father had unusually wide interests, extending from religion and social work not only into politics and philosophy but also into chemistry and biology, and these clearly influenced young John. His first formal contact with chemistry was at the Birmingham Technical School and so fascinated him that, when he had to leave the school to earn his living at the age of fourteen, he was "full of a desire to study chemistry" but "saw no hope whatever of doing so". However, to quote further from his autobiography, *The Land Called Me*, "thinking that chemistry was practised in chemists' shops, I decided to try and get into one and save up money to go to college". He got into one only to be disillusioned, but he was not easily put off and, with the persistence and energy that typified his whole life, he continued to study by attending evening classes and gained scholarships that took him in turn to the Presbyterian College, Carmarthen, to the University College of Wales, Aberystwyth, and, in 1894, to Owens College, Manchester.

Russell failed at his first attempt at the London B.Sc. degree, because his physics and mathematics were not up to standard. He then contemplated entering a theological college, but Prof. Dixon appointed him a research assistant at ten shillings a week, which allowed him to continue at Manchester, where to make ends meet he did other jobs as diverse as organist, reporter, lecturer, and coaching "some dull people through examinations that they never ought to have passed". At his second attempt he passed in the first division both the B.Sc. and the honours chemistry examinations, and then did research on various subjects, of which the most important was the oxidation of phosphorus, for which he was awarded the London D.Sc. degree in 1901. In addition to his chemistry, he was active as a social worker in the slums of Manchester, and, paradoxically, it was there that he first considered turning his attention to agriculture. He thought that many of those who failed to make good in cities would be happier and more prosperous in the country, and he had the idea of founding and leading a rural settlement where such people could be trained in agriculture. There were two major obstacles to implementing the idea: he had no money to found a settlement, and he knew nothing about agriculture. The second was the easier to overcome, so, against the advice of his seniors, who saw no future for a chemist in agriculture, when a lectureship became vacant at Wye Agricultural College, he applied for it, was appointed and started working there in January 1901. His social work played another important part in his life, for it was through it that he met Elnor Oldham, whom he married in 1903. They had six children, of whom five survive.

At Wye, Russell started the fruitful collaboration with A. D. Hall, principal of the College until 1902 when he moved to Rothamsted, that led among many other things to *The Soils and Agriculture of Kent, Surrey and*

*Sussex*, which provided the model for future surveys. As Russell saw more of practical agriculture, he increasingly appreciated not only the impracticability of his ideas about a rural settlement, but also that agriculture itself was woefully backward and urgently in need of research. His interests then changed and he turned his missionary zeal to getting scientific methods applied to agriculture; the career he was to follow so successfully had now begun. The course of lectures he gave at Wye on agricultural chemistry also formed the framework for his classic book *Soil Conditions and Plant Growth*, first published in 1912, which has passed through nine editions, the last two by his son, Prof. E. W. Russell, and has had a world-wide influence.

In 1907, Russell followed Hall to Rothamsted, where he was appointed Goldsmith's chemist, and in 1912 he succeeded Hall as director—a post he held with increasing distinction for thirty-one years. Hall did much to revive Rothamsted, where research had sadly declined from its peak in the earlier years of Lawes and Gilbert; but it was Russell who fashioned the comprehensive programme of research which now characterizes the Station. Russell was an able chemist and research worker and did some outstanding work on soils, particularly on partial sterilization, but his great achievements lie much more in the way he influenced the development of agricultural science than in his personal research. As a chemist interested in soils, it was to be expected that he would maintain and extend the work on crop nutrition that had made Rothamsted famous in the nineteenth century, but there were probably few other chemists who would have appreciated, as he did, the need for adding such diverse subjects as botany, physics, microbiology, entomology, pathology, biochemistry, statistics and the study of pesticides. Not the least of his qualities that helped to make his ventures succeed was his ability to judge people shrewdly and select able ones to act as leaders.

The extent to which he developed Rothamsted was all the more notable considering the spirit of the time when he did it. Except for a brief period after the end of the First World War, when neither the British Government nor people could fail to see the need for agriculture and the economic value of agricultural research, he got little official support for his proposals. In the 1930s when the Rothamsted Estate was up for sale, the Government was so uninterested that it did nothing to prevent it from being bought by a speculative builder; but Russell was undeterred by this lack of official backing, and with characteristic determination and enthusiasm raised the money to buy the Estate and preserve it for agricultural research. Similarly, he organized the centenary fund, which paid for the urgently needed new laboratories and glasshouses built in 1939. For these activities, all those who have since worked at Rothamsted and those still to come owe him an immense debt of gratitude.

In both World Wars, Russell served on many Government committees, dealing not only with agricultural subjects but also many others. His services as an adviser were also often sought by, and always willingly given to, many foreign Governments and organizations overseas. The value of these services to both agriculture and science is amply indicated by the list of honours and awards he received from British and foreign universities, academies, Governments and scientific societies—a list far too long to recount here. In all these, he took a due pride, but they left him free from conceit, never pompous or self-important, and always friendly and courteous.

Russell's memory, both for facts and people, was great. He seemed never to forget anyone he had

met or anything he had seen, read or heard. As he loved meeting people, travelled extensively and read widely, his knowledge was encyclopaedic, as is evidenced by his notable survey, *World Population and World Food Supplies*, published in 1954. An excellent lecturer and prolific writer, he dispensed information as readily as he acquired it. Always a keen supporter of the British Association, he rarely missed a meeting; he was its president in 1949, the first agricultural scientist to be elected to this position and perhaps of his many distinctions the one in which he took most pride.

A serious illness incapacitated him for a year shortly after he retired from Rothamsted; but he soon resumed a fully active life, not only continuing his writing and lecturing, but also his travelling. His interest in, and knowledge of, agricultural science was undimmed by age, and at ninety and more he was still asking the most penetrating questions, often dealing with subjects that had barely been born when he retired. His last visit to Rothamsted, to celebrate his ninetieth birthday, was an unforgettable occasion. He was his usual, lively self and without a note made a speech lasting more than forty minutes that was as memorable for his stimulating ideas about the current and future needs of agricultural research as it was for the wit and humour with which he recalled its history.

Only a man of exceptional ability, determination and energy could have achieved what he did, for during most of the first sixty years of his life he was continually battling to overcome difficulties and indifference to his aims. To have left school at fourteen and be elected to the Royal Society at forty-five is possibly unique, for self-made success is much rarer in research than in business or industry. But to have promoted agricultural research successfully in a period when a secretary of the then Board of Agriculture could say: "I cannot conceive the circumstances in which the board will be at all interested in scientific work", was a still greater achievement. The Royal Society of Arts awarded Russell the Albert Gold Medal—its greatest honour. The inscription reads, "For researches and leadership in agricultural science and services to husbandry in many lands"; although it fails to show that he also led a successful rebellion against ignorance and indifference, it is difficult to think of a more fitting epitaph.

F. C. BAWDEN

#### Dr. R. A. Alexander

RAYMOND ALBERT ALEXANDER died in Pretoria on July 8 at the age of sixty-six. He was born in Benoni, Transvaal, on July 29, 1899, and was educated at Jeppe High School, Johannesburg. After matriculating in 1915 he studied at the Potchefstroom School of Agriculture and was afterwards accepted for military training. In 1919 he went to the Transvaal University College and obtained the degree of bachelor of science, agriculture, in 1922. He then enrolled as a student in the newly formed Faculty of Veterinary Science under the renowned Sir Arnold Theiler and was awarded the degree of bachelor of veterinary science in 1925. In 1928 he joined the staff of the Veterinary Research Institute, Onderstepoort, and started his career as a virologist.

Having been awarded a fellowship by the Empire Marketing Board of Great Britain in 1931, Dr. Alexander studied at the Strangeways Institute, Cambridge, where he worked on tissue culture techniques under Dr. (now Dame) Honor B. Fell. During this time he also represented South Africa at the first Commonwealth Veterinary Conference in London. On his return to South Africa he continued his research work on virus diseases and produced original studies on the neurotropic virus of horse-sickness. As a result he was awarded a D.V.Sc. degree in 1935. In 1938 he again went overseas and worked for varying periods at the Rockefeller Institute, Harvard University, the Federal Bureau of Animal Industry and

the Canadian Veterinary Laboratory at Ottawa. When an extensive outbreak of horse-sickness occurred in Egypt and the Middle East during 1944, Dr. Alexander went to the assistance of the affected countries and was able to help control the scourge by means of the vaccine which he had developed at Onderstepoort.

He was appointed deputy director of veterinary services in 1949 and in that year took a leading part at the African Rinderpest Conference held in Nairobi, and the International Rinderpest Conference convened by the Food and Agriculture Organization of the United Nations. Later he served on a Commission appointed by the British Colonial Office to investigate veterinary problems and research in East African territories. In 1953 he was invited by the United States Government to visit America and to advise on the control of blue-tongue in sheep which was causing devastating losses.

Dr. Alexander was appointed director of veterinary services of the Union of South Africa in 1950 and served in this capacity for 11 years until he retired on superannuation.

He devoted his life to furthering veterinary science in general and virology in particular. As a result of his success in this respect he held many important posts, among which were the following: chairman of the Inter-African Bureau of Animal Health (1955-58); life vice-president of the South African Veterinary Medical Association; member of the Committee for Research into Medical Sciences of the Council for Scientific and Industrial Research; chairman of the Committee of the Virus Diseases Research Unit of the University of Cape Town; chairman of the Veterinary Board; member of the Technical Advisory Committee of the Poliomyelitis Research Foundation and of the Advisory Committee on Virology to the South African Minister of Health; consultant to the Food and Agriculture Organization of the United Nations/Office International des Epizooties at a world conference on emerging diseases held at Ankara.

Several honours came to Dr. Alexander. In 1955 he was awarded a D.Sc. (*honoris causa*) by the University of Cape Town and in 1957 he was elected a Fellow of the Royal Society (South Africa). In 1961 he was elected an honorary member of the Section of Comparative Medicine of the Royal Society of Medicine.

As a virologist, he gained a world-wide reputation and produced more than sixty scientific publications. He will be remembered for his enthusiastic participation in scientific meetings and his practical approach to animal disease problems.

B. C. JANSEN

#### K. A. Vlasov

KUZMA ALEXANDROVICH VLASOV, a prominent Soviet petrologist and geochemist, died on September 29, 1964. He was born in the Ryazan district of Russia on November 14, 1905. In 1931 he graduated in geology at the Timiryazev Academy and soon began field work on the Kola Peninsula under the guidance of A. E. Fersman. Starting with a study of beryllium minerals, Vlasov went on to investigate beryllium-bearing pegmatites, and this led in turn to an intensive study of granite-pegmatites in general. The results of his field observations were summed up in a comprehensive genetic-textural classification of granite pegmatites. His *magnum opus*, however, was his detailed work on the geology, petrology and geochemistry of the Lovozero alkaline massif on the Kola Peninsula. This was published in 1959. In 1953 Vlasov was elected a corresponding member of the Academy of Sciences of the U.S.S.R. and in the same year he was appointed director of the newly founded Institute of Mineralogy, Geochemistry and Crystallography of Rare Elements. The work of the Institute is being published in a three-volume edition (two volumes have already appeared), entitled *Geochemistry, Mineralogy and Deposits of Rare Elements*.

S. I. TOMCHENKO

## NEWS and VIEWS

Physical Chemistry in the University of Cambridge :  
Prof. R. G. W. Norrish, F.R.S.

ON September 30, Prof. R. G. W. Norrish will retire from the chair of physical chemistry in the University of Cambridge, a post which he has held with distinction for the past twenty-eight years. There can be few whose careers have been so completely linked with one city and its institutions. Norrish attended the Perse Grammar School in Cambridge, from which he entered Emmanuel College as a Scholar in 1915. He has since held a fellowship of that College for many years. Following war service, he took a double first in the Natural Sciences Tripos. He gained a Ph.D. in 1924 and an Sc.D. in 1936. He was appointed a demonstrator in physical chemistry in Cambridge in 1926, and later became Humphrey Owen Jones lecturer—a post which has been held by several physical chemists now occupying distinguished positions. He was elected a Fellow of the Royal Society in 1936 and in the following year became professor of physical chemistry at Cambridge. The great bulk of Norrish's work has been in reaction kinetics, much of it with a strong photochemical emphasis, and has been notable for a pronounced flair for clear experiments. Another interesting feature is the way it has taken the impact of the application of quantum mechanics in its stride. Norrish's attachment to photochemistry showed itself in early papers (1923) on potassium permanganate, and was followed by distinguished work on the effects of light on nitrogen dioxide and on chlorine. This led him into the fields of photosensitization and of chain reactions, in which he made outstanding investigations. His classical series of papers in the late 1930's on photolysis of aldehydes and ketones must also be mentioned.

All these lines have been pursued more recently, but the early 1950's saw the introduction of a remarkable new phase of activity based on flash photolysis and high-speed spectroscopic techniques, which enabled very rapid reactions and the details of exchange of molecular energy to be elucidated. This has been one of the most fruitful fields in which Norrish has worked, and to which, at the moment of retirement, he is contributing with distinction. Norrish's work has been recognized by foreign honours, among them an honorary doctorate of the University of Paris (Sorbonne), foreign membership of the Polish Academy of Sciences, and corresponding membership of the Academy of Sciences of Göttingen and of the Royal Society of Sciences of Liège. He has been president of the Faraday Society and vice-president of the Royal Institute of Chemistry. The quality of his research was recognized very early with the Meldola Medal of the Royal Institute of Chemistry in 1926, and confirmed by the awards of the Davy Medal of the Royal Society (1958) and the Faraday Medal of the Chemical Society (1964). He will be wished a long and active retirement by past members of his Department, who include eleven Fellows of the Royal Society, and by an enormous number of colleagues all over the world.

Prof. J. W. Linnett, F.R.S.

DR. J. W. LINNETT, reader in inorganic chemistry in the University of Oxford, who succeeds Prof. R. G. W. Norrish as professor of physical chemistry in the University of Cambridge in October, was educated at King Henry VIII School, Coventry, and at St. John's College, Oxford, where he was a pupil of Prof. H. W. Thompson.

After graduating in 1935 with first-class honours in chemistry he spent two further years in Oxford on research work for a D.Phil., and then went to Harvard for a year as a Henry Fellow. He returned to Oxford as a Junior Research Fellow of Balliol, and in 1945 was elected to a fellowship at The Queen's College. His first research interests were infra-red spectroscopy and molecular force fields, and later he turned to the application of quantum mechanics to problems of molecular structure. But although the author of numerous theoretical papers, he has also been actively involved in the experimental study of chemical kinetics, first of gaseous chain reactions by conventional methods, then of reactions in flames, and more recently of atom-recombination reactions. He has been prominent in administration, both in Oxford and elsewhere, being a vice-president of the Faraday Society and a secretary of the Chemical Society, and he has travelled and lectured widely. He was elected a Fellow of the Royal Society in 1955. Cambridge therefore gains, at Oxford's expense, a very talented physical chemist of wide interests and considerable experience.

Materials Technology in the College of Advanced  
Technology, Birmingham : Prof. H. J. Pick

DR. H. J. PICK has been appointed professor of materials technology in the Department of Metallurgy in the College of Advanced Technology, Birmingham (University of Aston in Birmingham designate), and will take up his new duties on September 1. On leaving Torquay Grammar School, Dr. Pick attended the University of Liverpool where, after a break of three years during the Second World War when he served as a pilot in the Royal Air Force, he obtained in 1949 a B.Sc. degree in engineering with honours in metallurgy. After a further two years at the University of Birmingham he was awarded a Ph.D. for research on industrial metallurgy. Dr. Pick is at present chief metallurgist with Joseph Lucas (Electrical), Ltd., Birmingham, and he previously held appointments as Research Fellow and as lecturer in industrial metallurgy at the University of Birmingham. He has carried out a considerable amount of research on casting and electro-deposition.

## Social Anthropology in the University of Hull :

Prof. I. G. Cunlison

PROF. I. G. CUNLISON has been appointed to the newly established chair of social anthropology in the University of Hull from January 1, 1966. Prof. Cunlison read for Part I of the Modern Languages Tripos at Cambridge before serving with the Royal Artillery during 1942–45. When he returned to Cambridge he took Part II of the Anthropology and Archaeology Tripos, graduating with first class honours. In 1952 he was awarded a D.Phil. degree by the University of Oxford, where he had been a research assistant in the Institute of Social Anthropology. After three years as research officer at the Rhodes-Livingstone Institute, Northern Rhodesia, he became an assistant lecturer in social anthropology in the University of Manchester. In 1952 he was appointed social anthropologist to the Sudan Government, and returned in 1955 to the University of Manchester, where he was Simon Research Fellow and later lecturer in social anthropology. He became head of the Department of Social Anthropology and Sociology in the University of Khartoum in 1959, where since 1964 he has been professor of social anthropology.

### Commonwealth Students in Britain

In a written answer in the House of Commons on July 16, Mr. A. E. Oram, the Parliamentary Secretary to the Ministry of Overseas Development, gave the number of students from each of the Commonwealth countries taking full-time courses in the United Kingdom in the academic years 1959-60-1963-64. To the total, which had risen from 30,169 in 1959-60 to 35,664 in 1960-61, 39,122 in 1961-62, 42,094 in 1962-63, and 42,322 in 1963-64, Nigeria, with 6,000, 6,800, 7,836, 8,954 and 8,630, respectively, was the largest individual contributor, followed by India, with 3,510, 3,400, 3,496, 4,281 and 4,129. Malaya, with 2,200, 2,220, 2,428, 2,496 and 2,882; Ghana (1,840, 3,793, 3,348, 1,885 and 1,991); Jamaica (1,940, 2,980, 3,151, 4,083, and 3,841); followed by Hong Kong (1,550, 1,580, 1,559, 1,619 and 1,715) and Pakistan (1,570, 1,245, 1,470, 1,711 and 1,924) came next. Trinidad and Tobago (1,100, 1,370, 1,622, 1,858 and 1,844) and Kenya (1,030, 1,272, 1,592, 1,532 and 1,593) were the only other countries to send more than 1,000 a year until 1960-61 when this figure was exceeded by Barbados; in 1961-62 it was also exceeded by Uganda, in 1962-63 by British Guiana, and in 1963-64 by Ceylon and Cyprus.

### Postgraduates at Universities in Britain

In a written answer in the House of Commons on August 4, Mr. A. Crosland, the Secretary of State for Education and Science, stated that the number of postgraduates at universities in Britain had risen from 1,400 in 1920-21 and 2,237 in 1930-31 to 11,327 in 1950-51, 12,668 in 1955-56, 17,836 in 1960-61 and 24,255 in 1964-65.

### Medical Research and Work Study

In a written answer on July 16, Mr. A. Crosland stated that expenditure by Government agencies, including the Medical Research Council, the Health Departments, Ministry of Defence, and the proportion devoted to medical research from the general grant to the universities, is estimated at £5.5 million in 1954-55, £6.5 million in 1955-56, and £7 million in 1956-57, rising to £14.5 million in 1961-62, £16 million in 1962-63, £18.5 million in 1963-64 and £23 million in 1964-65. No reliable estimate could be given of expenditure on medical research by other bodies including the pharmaceutical industry and voluntary organizations. During the academic year 1964-65, 623 students attended the Work Study School at the Royal College of Aeronautics, Cranfield, and, of its income of £55,165, £55,131 was from fees paid by sponsoring firms and organizations. For the same year, the College received a recurrent grant of £865,000 and non-recurrent grant of £96,005, as well as a capital grant of £28,995; for 1965-66 these were estimated at £825,000, £66,500 and £103,500, respectively. The College was the only exclusively post-graduate technological teaching institute of its kind in Britain, and the net cost per student had been reduced to a little more than £2,000 in the current year.

### Industrial Training Boards

In replying for the Government on July 29 to a Motion to annul the Industrial Training Levy (Engineering) Order, of June 11, 1965, Mr. R. Marsh, the Joint Parliamentary Secretary to the Ministry of Labour, said that the Engineering Board Levy of 2.5 per cent was likely to yield about £80 million in the first year. Direct Treasury assistance to the boards up to March 31 was about £135,000, apart from other assistance, such as senior staff, and during the current year direct Government grant to the boards would be about £1.5 million, compared with approaching £100 million from the levies, and none of this money would leave the industry. The Motion was withdrawn. In a written answer on August 2, Mr. R. J. Gunter, the Minister of Labour, who had previously given

the names of the chairman and deputy-chairman and members of the Ceramics, Glass and Mineral Industry Training Board, stated that, in January-June 1965, 35,434 boys and 5,717 girls gained apprenticeships on first entering employment, or 37.2 per cent and 6.5 per cent, respectively, compared with 34,221 (32.6 per cent) and 6,030 (6.1 per cent), respectively, in January-June 1964.

### In-Service Training for Teachers of Mathematics

THE serious shortage of teachers of mathematics will not be remedied by any single stroke, but one contribution to the solution of the problem lies in the development of in-service training, whereby those already teaching may be encouraged to revise and extend their knowledge of mathematics and so to fit themselves for coping with modern trends in mathematics and for undertaking greater responsibilities. Several institutes of education have provided excellent courses to this end, but much remains to be done, and the Joint Mathematical Council now offers a short report by its working party, in which a national scheme is propounded (*Report on In-Service Training for Teachers of Mathematics*. Pp. 12. London: Prof. J. G. Semple, Hon. Secretary, Joint Mathematical Council of the United Kingdom, c/o King's College, 1965). It suggests: (i) the setting up of mathematics centres to provide the necessary facilities, under local education authorities; (ii) the establishment by each institute of education of an advisory unit; (iii) that the Schools Council for the Curriculum and Examinations should set up a permanent sub-committee to recruit and train key personnel and to obtain necessary funds; (iv) the establishment of a national information centre to link together all people concerned and to provide information on all relevant topics. The report does not waste time and paper on deploring the present situation, but concisely and forcefully makes precise suggestions for the development and organization of a valuable constituent in any final solution of an urgent problem.

### Information and Communication

*Focus on Information and Communication*, recently issued by Aslib and edited by Barbara Kyle, includes seven papers (Pp. viii+113. London: Aslib, 1965. 14s.). It incorporates Barbara Wootton's two papers on problems in communications (reprinted from *Aslib Proceedings*, November 1963 and November 1964); A. R. Meetham's paper on preliminary studies for machine-generated index vocabularies (*Language and Speech*, January-March 1963); W. T. Williams's paper on "Computers as Botanists" (*Nature*, 179, 146; 1963); R. Crawshaw-Williams's paper on "The Double Criterion of Empirical Judgment" (previously circulated privately in duplicated form); Prof. P. Meredith's "Documents, Programmes and Topics—Some Observations on Topic Analysis" (based on two earlier papers on topic analysis and an analysis of relations); Prof. J. K. Feibleman's "The Integrating Levels in Nature" (a revised version of an earlier paper in the *British Journal for the Philosophy of Science* in 1954).

### Scientific Information Notes

THE June-July 1965 issue of *Scientific Information Notes* (7, No. 3; 1965), issued by the National Science Foundation, includes further information on the two-year experimental programme to provide a rapid source of chemical information for which the Science Adviser to the President has announced a 2-million dollar contract between the Foundation and the American Chemical Society. It provides for the establishment, by the Society's Chemical Abstracts Service, of a computer-based registry system for chemical compounds based on chemical structure and for selected research. It is expected that

some 400,000 references will be fed into the system each year, of which 75,000 will be to new compounds, and the system will identify any compound which has previously been processed and assign the same number to it each time it appears. The Federal Council for Science and Technology has made a task group of its Committee on Scientific and Technical Information responsible for developing a long-range plan for improving national scientific and technical information systems. The Atomic Energy Commission and the National Bureau of Standards are jointly sponsoring an Atomic and Molecular Processes Information Centre at the Oak Ridge National Laboratory to collect, store, evaluate and disseminate information from all over the world relating to atomic and molecular cross-section and other particle collision processes in the three areas: interaction of heavy particles; particle penetration through matter; excitation, dissociation, ionization and detachment by external electric and magnetic fields.

#### The Royal Ontario Museum, University of Toronto

THE annual report of the Royal Ontario Museum for the year July 1963–June 1964 is of special interest in that it records the reorganization that has been undertaken by the new director, Prof. W. E. Swinton, late of the British Museum (Natural History) (Pp. 16. Toronto: Royal Ontario Museum—University of Toronto, 1965). In brief, the director now takes a larger place in the University, becoming a member of the Senate, and of the Council of the Faculty of Arts and Sciences. In the Museum he is responsible for general policy, curatorial matters, display and academic publication. The Associate Director is responsible for the non-curatorial staff, and for day-to-day administration. The abolition of the divisional structure gives a large measure of autonomy with, of course, increased responsibility to each of the departments. All curators have direct access to the Director, and each has inaugurated research programmes of a high order. This new upsurge of activity has already borne fruit in the form of publications completed during the year and now in the press. In several cases some of this work has been done jointly with other institutions, for example, with McGill University in ichthyological researches in Barbados, and with the National Museum of Canada in an anthropological project.

#### The Museums and Art Gallery, Leicester

THE fifty-eighth report of the Committee of the City of Leicester Museums and Art Galleries, for 1963–64, records that much thought has been given to the establishment of a museum of science and technology (Pp. 13. Leicester: The Museums and Art Gallery, 1965). The popular interest shown in industrial archaeology indicates that this is a growing study, the importance of which should be reflected in the Museums. However, material is being collected and this eventually will form the nucleus of the collections. The new Museum of Archaeology on the Jewry Wall has been completed and the Committee has plans to tidy up the Newarke Gateway. An interesting appointment was that of Mr. G. J. Bemrose, late director at Stoke-on-Trent Museums, to advise on the purchase of ceramics—a branch of applied art in which the Museum's collections were curiously deficient. Although the Committee is continuing to train student-assistants and appoint trainee-assistants, there is still a dearth of officers for the more senior posts, and most of the departments of the Museum are understaffed. The report is well illustrated, has an arresting cover, and concludes with an impressive list of acquisitions.

#### Atlas of the Antarctic

THE weekly journal of the Russian book trade, *Novye Knigi*, announces the forthcoming appearance, late in 1965, of a major *Atlas of the Antarctic*, to be published by

the Main Administration for Geology and Cartography (GUGK) of the U.S.S.R. The work will incorporate the results of the cartographical, geological and geophysical researches of the twelve nations which have collaborated in Antarctic work during and since the International Geophysical Year. It is planned in two volumes, the first of which (Pp. 300, size 38 × 60 cm., price 30 roubles) will comprise maps of all kind, and the second (price 5 roubles) an explanatory text. Orders placed through the national agencies for Russian books should quote *Novye Knigi* 25–1965, item 21.

#### Scottish Field Studies

THE Scottish Field Studies Association opened its Field Studies Centre at Kindrogan, Perthshire, in November 1963, and, in its annual report for 1964, reviews the Centre's activities to date (Pp. 25 + 4 plates. Glasgow: The Scottish Field Studies Association, 1965. 5s.). During the first season, 502 students attended, 134 taking courses in geography, 72 in biology, 175 in botany and 121 in a combined course of biology and geography. 214 of the students came from schools, 110 from universities and technical colleges, 54 from training colleges and 124 paid 'unattached' visits. With its attractive facilities, Kindrogan should gain increasing support; however, although it has received generous financial support from educational bodies, the complete lack of response to an appeal from Kindrogan to Scottish industry is not only lamentable but shows how short-sighted industrialists can sometimes be.

#### Comparison of Colorimeters

THE Association of Clinical Biochemists has published Scientific Report No. 1, entitled *Colorimeters Fitted with Flow Through Cells* (Pp. 54. Liverpool: J. T. Ireland, Biochemistry Laboratory, Alder Hey Children's Hospital, 1965. 13s. 6d.; Association members, 8s. 6d.). In these instruments, the optical densities of a number of solutions, for example a batch of blood haemoglobin solutions, can be measured without removing the optical cells from their holders. The report gives a detailed and critical appraisal of four commercial colorimeters of this type. All four contained a selenium photocell and the wave-length band was selected by use of colour filters or an interference wedge. The report also covers such topics as maintenance, faults developing during use and the adequacy of the instruction booklets. The methods developed for assessing the performance of the instruments should be helpful to anyone wishing to test the performance of any colorimeter. The report should also be helpful to manufacturers anxious to improve the design and reliability of their instruments.

#### Progress In Concrete Research

As forecast in the previous report for 1963 (*Nature*, 204, 233; 1964), the Hon. Leo Russell, director-general of the Cement and Concrete Association, in his introduction to the report for 1964 confirms that the increase in the financial resources of the Association has been reflected in each of its main fields of activity during that year (Pp. 116. London: Cement and Concrete Association, 1965). In research and development projects, special mention is made of the work on factors affecting skidding resistance of concrete roads at high speed, carried out in close collaboration with the Road Research Laboratory; on investigations of surface appearance of *in situ* concrete, culminating in the symposium organized jointly with the Royal Institute of British Architects in October 1964; and on the introduction of 'Standard Mixes' by the committees responsible for the preparation of the new *Code of Practice for Precast Concrete* (CP 110) and for amendments to the *Code of Practice for Reinforced Concrete* (CP 114). Further developments in the matter of standard prestressed precast concrete beams for bridges are also

noteworthy. The continuing research on materials, design of concrete structures, and on methods of construction is adequately catalogued. On the materials side are discussed fundamental properties of unstressed concrete; properties of concrete under stress; durability of concrete; X-ray diffractometry of cement minerals; the system  $\text{CaO-Al}_2\text{O}_3\text{-SO}_3$ ; hydration of cement; problems of chemical analysis of cement and concrete; research on concrete under stress; elasticity of high-strength concrete; damping capacity; concrete strength testing; relationship between bending strength of reinforced concrete beams and concrete cube strength; perlite aggregate concrete; and dimensional changes in unloaded concrete. In the section recording research on design of structures, among other subjects, mention is made of the work on bridges; doubly curved shell roofs; ultimate load behaviour of framed structures; analysis of shear walls in multi-storey structures; and model testing of structures. Methods of construction include work on factors affecting appearance of concrete surfaces; on omission of expansion joints from concrete roads; on skidding resistance; and on no-fines concrete for paving. Looking ahead, there is immense scope for development of precast concrete structural units based on standard mould sizes; the increased capacity planned for production of high-quality concrete facing blocks should materially help to relieve the present shortage of building bricks.

### Prestressed Concrete and Machinery Structures

A SYMPOSIUM on the "Application of Prestressed Concrete to Machinery Structures" was held during January 14-15, 1964, at the Conference and Training Centre of the Cement and Concrete Association, Wexham Springs, Slough, Buckinghamshire, on behalf of the Committee set up to examine this subject by the Fédération Internationale de la Précontrainte. The *Proceedings* of this symposium have recently been published by the Prestressed Concrete Development Group (Pp. 40. London: Prestressed Concrete Development Group, 1965. 25s.). Following a brief address of welcome by A. R. Collins (director, Research and Technical Services, Cement and Concrete Association), the opening address was delivered by Y. Guyon (président, Fédération Internationale de la Précontrainte) wherein he described the subject as "... certainly a fascinating one, and the field so far is almost virgin, with a tremendous potential for development". The papers which followed were: "Prestressed Concrete and its Relevance to Machine Frames" by A. J. Harris; and "Local and Bearing Stresses" by R. E. Rowe. Under the general heading "Applications of Prestressed Concrete to Machinery Structures", six papers were presented: "Power Stations" by C. D. Crosthwaite; "Dynamic Loading" by J. H. A. Crockett; "Some Structures subject to Shock Loading" by F. Walley; "Foundations for Heavy Plant" by Th. Hinckeldey and R. Oppermann (West Germany); "Presses and Plant for Heavy-Metal Cutting" by J. T. Lewis; and "Triaxially Prestressed Bedplates or Heavy Frames" by I. G. Ludkovsky (U.S.S.R.). The summing up and general conclusions reached at this symposium were left to A. J. Harris and are given at the end of this publication, which certainly breaks new ground and for this reason alone is an important contribution to our knowledge of the use and scope of prestressed concrete.

### Magnetism Group

THE Council of the Institute of Physics and the Physical Society has announced the establishment of a Magnetism Group. The aim of the new Group is to further interest in magnetism by holding regular discussion meetings and in other ways. It is intended that these meetings shall be of relevance to physicists from industry, Government establishments and academic institutions and co-operation will be maintained with

other specialist groups of the Institute and Society, and with similar groups at home and abroad. The first meeting of the new Group will be held in December 1965 and further details will be announced later. The following have been appointed as the provisional Committee and granted power to co-opt additional members: Dr. W. M. Lomer (chairman); Prof. E. B. Wohlfarth (honorary secretary); Dr. G. G. E. Low; Mr. R. D. Lowde and Dr. W. Marshall. Further information, including details of membership of the Institute and Society and of its Magnetism Group, can be obtained from the Registrar, the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

### Announcements

MR. R. ORGAN, formerly chief experimental officer in the research laboratories of the British Museum, has been appointed curator of conservation at the Royal Ontario Museum.

THE bicentennial celebration commemorating the birth of James Smithson will be held at the Smithsonian Institution during September 16-18. Further information can be obtained from the Smithsonian Institution, The Mall, Washington 25, D.C.

A SYMPOSIUM on "Insect Behaviour", arranged by the Royal Entomological Society of London, will be held at the Imperial College of Science and Technology during September 23-24. Further information can be obtained from the Registrar, Royal Entomological Society of London, 41 Queen's Gate, London, S.W.7.

A SYMPOSIUM on "The Soil Resources of Tropical Africa", organized by the African Studies Association of the United Kingdom, will be held at University College, London, on September 29. Further information can be obtained from Prof. J. D. Fage, Centre of West African Studies, University of Birmingham, Birmingham 15.

A CONFERENCE on "Optics in Space", arranged by the Optical Group of the Institute of Physics and the Physical Society, will be held at the University of Southampton during September 27-30. Further information can be obtained from the Meetings Officer, Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

A CONFERENCE on "Non-metallic Thin Films", arranged by the Electronics Group of the Institute of Physics and the Physical Society, will be held at Chelsea College of Science and Technology during September 23-24. Further information can be obtained from the Meetings Officer, Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

THE twentieth annual "Electronics, Instruments, Controls and Components Exhibition and Convention" of the Institution of Electronics (Northern Division) will be held at Belle Vue, Manchester, during September 28-October 2. Further information can be obtained from Mr. W. Birtwistle, Institution of Electronics, 78 Shaw Road, Rochdale, Lancashire.

**CORRIGENDUM.** In the article entitled "Mitosis in Hybrid Cells derived from Mouse and Man" by Prof. H. Harris *et al.*, which was published on p. 606 of the August 7, 1965, issue of *Nature*, the blocks for Figs. 1 and 2 should be interchanged. The legends should stand as at present.

**ERRATUM.** In the article entitled "Correlation between Coding-triplets and Amino-acids" by Dr. S. R. Polo, which appeared on p. 597 of the August 7, 1965, issue of *Nature*, lines 8 and 9 of the second paragraph should read "... No amino-acid in these columns contains a methyl group".

## LIBRARY AND INFORMATION SCIENCES EXHIBITION

By D. L. SMITH, Librarian  
Oxford College of Technology

IN Great Britain library work is still generally considered to be one of the gentler professions, even more perhaps among the dreaming spires of the "home of lost causes" than in industrial cities. Librarianship has not yet been recognised as the library science of the United States. It may seem surprising, therefore, that Oxford should be the centre for an exceptionally comprehensive exhibition of literature devoted to library and information sciences. It is less surprising that a large proportion of the material displayed should have been American, especially in the documentation and information retrieval aspects which were particularly emphasised.

The exhibition was arranged by the Documentation and Supply Centre of Robert Maxwell and Co., Ltd., in their Oxford bookshop below the new buildings of Magdalen College, during July 29-31. Its opening on the first afternoon was attended by a representative cross-section of the academic, technical and scientific library, information officer and book-selling professions and, in the absence of Mr. Robert Maxwell on parliamentary duties, the objectives were explained by Mr. Cadmus Page, who has recently become managing director of the firm's book-selling service. Mr. Page briefly outlined the new imperative need of research workers in every field for rapid, accurate and thoroughly comprehensive literature searches, and said it was fortunate that the much-publicized information explosion had been followed by the introduction of computers, automatic control and punched-card techniques into the processes of documentation and information retrieval. This was the first exhibition of its kind to be held in Britain, and as such was a vital contribution to scientific research. A special value of the occasion lay in the opportunities for informal discussion of present-day problems among the participants.

Tribute was paid to the work of Mr. Hans Zell, in charge of Maxwell's Documentation and Supply Centre, who was responsible for collecting the extremely wide range of literature on display. The office of the Centre, with its permanent collection of bibliographical tools, unrivalled except in the larger university libraries, was also open to visitors; likewise the new warehouse (with storage space for more than three million volumes) and offices, now nearing completion half a mile away at Headington Hill Hall on the site shared with Pergamon Press, which have been planned for the improvement of the firm's nationwide and international service for the supply of books to libraries. Mr. Zell is already well known as editor of a number of other useful lists and bibliographies distributed to librarians, including *New Reference Tools for Librarians* of which the third annual volume has just appeared; subject bibliographies on a wide range of topics, such as cartography, nutrition, graphic arts and industries, quality control and biophysics, all international in their coverage; and the new 300-page *International Bibliography of Non-periodical Literature on Documentation and Information*, the publication of which coincided with the opening of the exhibition. More specific in its content, the latter gives full details of more than 1,500 items published since 1930 (Russian material being excluded), with appendixes devoted to relevant periodicals and associations; arrangement is alphabetical, with a manually produced, permuted title index, and it is planned that a more useful subject index, produced by computer, will be incorporated in a later edition.

Another service operated from the same Documentation and Supply Centre, and now firmly established, is the punched-card system giving advance information on new books, batches of cards being distributed free to individual libraries on the basis of their own subject coverage.

In support of the exhibition the same editor has issued an attractive and clearly laid-out catalogue of its contents, with a supplement to bring it right up to date—nearly 800 books and pamphlets from eighteen countries altogether. While the emphasis is on modern methods of storing and speedily retrieving information in print and in every recorded form—the mechanized systems available for cataloguing, indexing, storage, location and extraction—the exhibition also embraced every branch of library science and librarianship in the more traditional sense, and includes a comprehensive range of recently published bibliographies, encyclopaedias and other reference books in every field likely to be of use to the librarian or reader in search of information. All the material has appeared since the beginning of 1963, and there were a few proof copies of books to be published shortly, such as the next two volumes in the "How to Find Out" series from the Commonwealth and International Library of Science, Technology, Engineering and Liberal Studies, of Pergamon Press. One section of the exhibition was devoted to specimen copies of recent journals dealing with information processing, storage and retrieval.

Perhaps the most notable feature of the display and its accompanying catalogue was the success of the efforts made to include a great deal of ephemeral, obscure and out-of-the-way material, such as bibliographies or specialized papers issued by libraries, schools of librarianship, research establishments and some of the less-well-known Government organizations. Many of these are unlikely to be listed in regular national bibliographies or publishers' catalogues. The means by which so many obscure pamphlets had been traced and assembled was a mystery to at least one librarian, and the opportunity of examining so much material of this nature in itself made the whole operation well worth while. This achievement was all the more remarkable in view of the fact that some of the libraries originally approached for details of their publications apparently did not reply at all. Of the catalogue there can be only one small criticism: a contents list of the broad subject headings governing its arrangement would have been helpful, unless it is realized that they are in Universal Decimal Classification order.

From such a wealth of material it is impossible to pick out any items more worthy of notice than others; the smallest and least conspicuous were often as valuable as the largest tomes. Among the latter J. G. Davis's two interesting volumes on *Chaos* seemed at first sight out of place, until it was realized that Volume 2 consists entirely of an annotated bibliography with subject index.

It was perhaps a little unfortunate that the exhibition should have been held at the peak of the holiday season, when many librarians and information scientists were far away; and undoubtedly in London it would have attracted even more attention. The sponsors have announced, however, that it is being repeated at the Library Association Conference at Eastbourne in September, and in Scotland at Maxwell's Glasgow bookshop and Cairns Brothers of Edinburgh; possibly also at Aslib headquarters in London.

## PUBLIC EXAMINATIONS AT OXFORD

THE report of the Committee on the Structure of the First and Second Public Examinations of the University of Oxford, issued in March 1965 as Supplement No. 3 to the *University Gazette* (and now published separately\*), has thirty-two principal recommendations. The first of these is that, since the normal period of study for the first degree cannot be extended beyond three years, more of the top third of the students should be encouraged to stay on, either for a second Honours School or for a B.Phil. or Diploma course. No form of the First Public Examination should be based on less than three terms' work in the University, and the B.A. course should normally be divided so that each undergraduate without senior status has the opportunity of taking two examinations, each of medium size. Nevertheless, any faculty which so desires should be allowed to maintain an undivided Honour School at which candidates can satisfy the requirements of the First Public Examination and the Second Public Examination together at one time.

Provision is also recommended for new combinations of subjects and for "high level conversions" without reducing the standard of honours work and without multiplying separate examinations or special arrangements between faculties. New joint Schools linking the natural sciences and the humanities should be instituted where desirable by special arrangement on the patterns of the Final Honour School of Engineering and Economics. Teachers of the natural sciences in the university are recommended to consider together the possibility of establishing a comprehensive and integrated form of First Public Examination. This would give all students of science what they need in their first year while facilitating

the choices and changes which may be desirable before undergraduates are committed to their Final Honour Schools. The offer of supplementary subjects in a natural sciences course should be further encouraged and Honour Moderations in Classics and Theology retained as examinations to be taken after five terms.

On evidence of ability and industry supplied by his college, an undergraduate, unable by reason of sickness to sit Honour Moderations at the normal date, should be allowed to proceed with his studies as though he had passed, and the normal period of study for a single subject Final Honour School in modern humanities should be four terms for candidates who have already taken an Honour Moderations course of five terms. However, in appropriate cases a candidate who has already taken one such Final Honour School should be encouraged to offer himself for examination in another one year later. It should be possible for selected undergraduates to prepare themselves for examination in two short Final Honour Schools together seven terms after Honour Moderations, and the administration of the new arrangements suggested in the report should be entrusted to two new Boards, one for science and one for humanities.

Abolition of the Pass School is recommended, but an undergraduate who has to abandon hope of finishing a full Honours course should be given credit for what he has already done and be able to qualify for a degree, either by a reduced version of what he originally intended or by a wider and more elementary course constituted from pieces of the First Public Examination. Discussion of the structure of the University's examinations should proceed on the assumption that the University year will not be changed, and the University should negotiate with other British universities for greater uniformity in the titles of higher degrees.

\* University of Oxford. Report of the Committee on the Structure of the First and Second Public Examinations. (Supplement No. 3 to the *University Gazette*, March 1965.) Pp. 141. (Oxford: The University, 1965) 10s.

## CODING RESPONSE OF N-FORMYL-METHIONYL-sRNA TO UUG

By DR. B. F. C. CLARK and DR. K. A. MARCKER

Medical Research Council Laboratory of Molecular Biology, University Postgraduate Medical School, Cambridge

RECENTLY, it was established that methionyl-sRNA is partly converted to N-formyl-methionyl-sRNA in a cell-free system from *Escherichia coli*<sup>1</sup>. The function of N-formyl-methionyl-sRNA in relation to the biosynthesis of protein has not been elucidated so far. We have investigated the coding characteristics of methionyl-sRNA and of N-formyl-methionyl-sRNA by using them as sources of amino-acids for polypeptide synthesis in a cell-free system and by binding them to ribosomes in the presence of specific triplets.

Studies of the T-1 ribonuclease digestion products of unfractionated partially formylated methionyl-sRNA showed that at least two methionyl-sRNA species exist in *E. coli*, and at least one of them cannot be formylated<sup>2</sup>.

Nirenberg's group first reported that poly UG stimulated the incorporation of methionine into protein-like material<sup>3</sup>, but their later preparations of poly UG failed to do so<sup>4</sup>. Because preparations of poly UAG and of poly UAGO stimulated methionine incorporation, the codeword UAG, of unspecified sequence, was assigned to methionine<sup>4,5</sup>. In recent months, most possible ribonucleotide triplets of specified sequence have been assigned to one or other of the 20 naturally occurring amino-acids<sup>6,7</sup>,

using the elegant technique of Nirenberg and Leder<sup>8</sup>. In particular, methionyl-sRNA was found to be coded for by the triplet AUG<sup>7</sup>.

We have been able to repeat the earlier observation that poly UG stimulates the incorporation of methionine into polypeptide using a partially purified *E. coli* cell-free system with negligible formylation activity and a polymer with a base analysis of U/G=1.8/1. When N-formyl-methionyl-sRNA or the means of formylation were added to the cell-free system, there was a clear increase in the rate of incorporation of methionine into polypeptide (Fig. 1).

We investigated the nature of a polypeptide product synthesized *in vitro* in a system involving an S-30 fraction<sup>10</sup> from *E. coli* MRE 600, poly UG, and a mixture of unfractionated methionyl-sRNA and N-formyl-methionyl-sRNA. The amount of <sup>35</sup>S-methionine incorporated in this system was about 12 per cent that of <sup>14</sup>C-phenylalanine. Interestingly, the analysis of the TCA-insoluble material revealed that 80-90 per cent of the incorporated methionine occurred as N-terminal N-formyl-methionine. This suggests that only the methionyl-sRNA which can be formylated responds to poly UG in a protein-synthesizing system.

Fig. 1. Incorporation of  $^{35}\text{S}$ -methionine from unfractionated  $^{35}\text{S}$ -methionyl-sRNA. The reaction mixture (0.5 ml.) contained 80  $\mu\text{moles}$  *tris*,  $\text{HCl}$  pH 7.4, 80  $\mu\text{moles}$  ammonium acetate, 5  $\mu\text{moles}$   $\text{MgCl}_2$ , 2  $\mu\text{moles}$  phosphoenolpyruvate, 0.5  $\mu\text{moles}$  ATP, 0.1  $\mu\text{moles}$  GTP, 5  $\mu\text{g}$  pyruvate kinase, 2  $\mu\text{moles}$  mercaptoethanol, 11.2  $A_{260}$  units of *E. coli* *MRE* 600 ribosomes, 150  $\mu\text{g}$  of a partially purified transfer enzyme fraction and 200  $\mu\text{g}$  of  $^{35}\text{S}$ -Met-sRNA ( $1.6 \times 10^5$  c.p.m.;  $1.6 \times 10^5$  c.p.m. = 1  $\mu\text{mole}$ ) which was charged in the presence of the  $^{14}\text{C}$ -amino acids minus methionine<sup>1</sup>. The ribosomes were purified further, after the usual washing, by chromatography on a DEAE-cellulose column<sup>2</sup>. During the incubation at 30° C, 50  $\mu\text{l}$ . samples were removed at the times indicated and added to tubes containing 100  $\mu\text{l}$ . each of 0.5 per cent bovine serum albumin solution. The polypeptide products were precipitated with 10 per cent TCA and then heated at 90° C for 15 min before being collected on 'Oxoid' filters. The radioactivity on the filters was assayed in a Nuclear Chicago thin-window gas flow counter. The curves represent: (1) No polymer added. (2) The presence of 20  $\mu\text{g}$  of poly UG and unfractionated Met-sRNA. When 125  $\mu\text{g}$  of purified transformylase<sup>3</sup> was added the same results were obtained as for curve 2. (3) As for curve 2 but with the addition of 100  $\mu\text{g}$  of *N*-formyl-tetrahydrofolic acid and transformylase. (4) As for curve 2 without transformylase but with about 60 per cent of the Met-sRNA converted into *N*-formyl-Met-sRNA.

Using the binding assay described by Nirenberg and Leder<sup>4</sup>, we obtained the results shown in Table I. Briefly, both a mixture of all methionyl-sRNAs labelled with

Table I. BINDING OF AMINO-ACYL-sRNA TO RIBOSOMES STIMULATED BY TRI- AND POLY-NUCLEOTIDES

Addition ( $A_{260}$ units)	$^{35}\text{S}$ -Met-sRNA ( $\mu\text{moles}$ of Met)	$^{35}\text{S}$ - <i>N</i> -formyl-Met-sRNA ( $\mu\text{moles}$ of Met)
Exp. I		
None	0.14	0.16
UUG (0.20)	1.51	1.74
AUG (0.25)	1.99	2.00
Poly UG (0.40)	0.32	0.34
Poly AUG (0.12)	0.44	0.37
Exp. II		
None	0.06	
UUG (0.24)	0.70	
AUG (0.20)	1.50	
Poly UG (0.20)	0.48	

Conditions for binding were similar to those described by Nirenberg and Leder<sup>4</sup>. The sRNA from *E. coli* B was charged according to Marcker and Sanger<sup>5</sup> but in the presence of 19  $^{14}\text{C}$ -amino-acids. In experiment I, 9.7  $\mu\text{moles}$  of  $^{35}\text{S}$ -*N*-formyl-Met-sRNA or 12.5  $\mu\text{moles}$  of  $^{35}\text{S}$ -Met-sRNA with specific activity of 900  $\mu\text{Ci}/\mu\text{mole}$  were added to the reaction mixture which contained 3.25  $A_{260}$  units of *E. coli* D21/4 ribosomes. Analysis of the polymers gave U/G = 2/1 for poly UG and U/A/G = 4/1/1 for poly UAG.

In experiment II, 6.3  $\mu\text{moles}$  of  $^{35}\text{S}$ -Met-sRNA with specific activity of 2,000  $\mu\text{Ci}/\mu\text{mole}$  were added to a reaction mixture, 0.01 M in  $\text{Mg}^{++}$ . The ribosomes (1.8  $A_{260}$  units) and poly UG were samples of preparations described in Fig. 1.

$^{35}\text{S}$ -methionine (not formylated) and a preparation consisting mostly of *N*-formyl-methionyl-sRNA responded significantly to the triplets UUG and AUG. Recovery and hydrolysis at pH 10 of the bound *N*-formyl-methionyl-sRNA yielded *N*-formyl-methionine, showing that the binding process did not remove the formyl group.

Although the codeword UUG has been suggested for leucine by the binding assay<sup>11</sup> and by the finding that the amber codeword, which is thought to be UAG, spontaneously reverts to a leucine codeword<sup>12</sup>, we propose that in certain circumstances UUG is a codeword for methionine. To clarify our results, investigations using fractionated sRNA are in progress.

## RNA OF LOW MOLECULAR WEIGHT IN RIBOSOMES OF MAMMALIAN CELLS

By F. GALIBERT, C. J. LARSEN, J. C. LELONG and M. BOIRON

Laboratoire d'Hématologie Expérimentale, Institut de Recherches sur les Leucémies, Hôpital Saint-Louis, Paris X<sup>e</sup>

THE presence of RNA of low molecular weight linked to ribosomes in *E. coli* has been reported by several authors (Elson<sup>1,2</sup>, Roesset and Monier<sup>3</sup>, Roesset, Monier and Julien<sup>4</sup>) and its presence in *Blastocladiella emersonii* has been reported by Comb and Katz<sup>5</sup>. According to Roesset *et al.* and Comb *et al.*, this nucleic fraction is heterogeneous when chromatographed on methylated albumin columns (MAK), and is composed of transfer RNA and another fraction called '5S' RNA by Roesset *et al.* We noted in preparations of KB cells and rat liver the constant presence, on the methylated albumin chromatograms, of a peak eluted under the same conditions as those described by these authors. This report describes some properties of this RNA.

KB cells (human epidermoid carcinoma line) were cultivated in Roux bottles and grew exponentially in

monolayers with an average generation time of 24 h, in a casein hydrolysate medium supplemented by 15 per cent of calf serum. The cells were gathered by scraping the wall. Preparations were also made starting with liver cells of male Wistar *OF* rats weighing about 15 g. The animals were killed by decapitation after fasting for 24 h.

Labelling of the KB cells with  $^{32}\text{P}$  was obtained by cellular growth with 2  $\mu\text{Ci}/\text{ml}$ . in a casein hydrolysate medium buffered with *tris* and supplemented by 15 per cent of calf serum dialysed against 0.15 M NaCl.

Total RNAs were extracted from cells disrupted by 0.5 per cent of purified sodium dodecylsulphate in  $2 \times 10^{-3}$  M sodium acetate buffer, pH 5.1, and then deproteinized with an equal volume of freshly distilled and water-saturated phenol.

Fig. 1. Chromatographic pattern of total RNA of KB cells: 1.5 mg of phenol-extracted RNA was loaded on MAK column and eluted by linearly increasing NaCl (from 0.2 M to 1.2 M) with phosphate buffer at pH 6.9 (3 ml./tube). The peak of '5 S' RNA is indicated by an arrow

Fig. 2. Chromatographic pattern on MAK column of RNA from ribosomes of KB cells labelled with  $^{32}\text{P}$ . Cold KB cells were added as a carrier before extraction (a, optical density; b, radioactivity)

Soluble and ribosomal RNA were extracted respectively from 105,000g supernatants and centrifugation pellets from disrupted cells in Hoegland medium<sup>8</sup> plus sodium deoxycholate (0.6 per cent). All manipulations were carried out at 4° C.

The methylated albumin columns were prepared and loaded according to Mandell and Hershey<sup>7</sup>, and were eluted by a sodium chloride gradient from 0.2 M to 1.2 M in 0.05 M phosphate buffer at pH 6.9.

Base composition was determined by the procedure of Katz and Comb<sup>9</sup>. The assay of the methylated bases and of pseudo-uridylic acid was carried out in accordance with Roesset *et al.*<sup>4</sup>.

The total RNA chromatograms of the KB or rat liver cells showed the usual fractions already described by several authors (see Philipson<sup>6</sup>): one peak of transfer RNA and two peaks of ribosomal RNA respectively eluted by 0.42 M, 0.80 M and 0.90 M NaCl (Fig. 1).

The DNA was eluted by 0.65 M NaCl. The size of this peak varied somewhat but was always low under the extraction conditions used.

With an average molarity of 0.50 M NaCl, a peak which overlapped that of transfer RNA and represented about 10 per cent of the latter appeared for both types of cells. Since there was a reasonable agreement between the ribose determination and the ultra-violet absorption at 2600 Å, and since the material of this peak was sensitive to the action of the RNase and resistant to the action of the DNase, we concluded that it was certainly composed of RNA.

The intracellular localization of this fraction could be illustrated by differential extraction. Chromatography of RNA extracted from ribosomes showed that the importance of this new fraction increased considerably in relation to the transfer RNA (Fig. 2). Moreover, this fraction was absent in the chromatograms of RNA extracted from 105,000g supernatants (Fig. 3).

Since we could obtain, after extraction from ribosomes and chromatography on methylated albumin, a '5 S' RNA containing less than 5 per cent of transfer RNA, but with a poor recovery, the purification of the '5 S' RNA was successfully obtained by subjecting the total RNAs to repeated chromatography on methylated albumin. An alternative method was by gel filtration on 'Sephadex' G100 (190 × 1.8 cm columns-elution by 0.05 M ammonium acetate, pH 5.1; Virmaux *et al.*<sup>10</sup>). Under these conditions, the '5 S' RNA was eluted between ribosomal RNA and transfer RNA (Fig. 4).

A few separation tests by ultracentrifugation in a 5–20 per cent sucrose gradient (in acetate 0.01 M buffer, pH 5, containing 0.1 M NaCl) showed that the sedimentation coefficient was slightly greater than that of the transfer RNA. These results agreed with the gel-filtration experiments.

Although the analysis of the base composition showed a great analogy between the two RNAs '4 S' and '5 S', a

Fig. 3. Chromatographic pattern on MAK column of RNA extracted from 105,000g supernatants of disrupted KB cells (two one-hour centrifugations at 105,000g)

Fig. 4. Chromatographic pattern of total RNA (2 mg) of KB cells on 'Sephadex' G100 column (190 cm × 1.8 cm) eluted by 0.05 ammonium acetate pH 5.1 (4 ml./tube)

statistical study of the results by means of Student's *t* test confirmed that the base composition was significantly different for U, C and A ( $P < 0.01$ ). Moreover, there were no methylated bases or pseudo-uridylic acid (which are characteristic of the transfer RNA) in the '5 S' RNA (see Tables 1 and 2).

Table 1

	U (+pseudo U) (%)	G (%)	C (%)	A (%)
Transfer RNA	27.16	30.97	25.33	16.53
'5 S' RNA	24.68	31.01	25.33	17.66

Means of four transfer RNA and five '5 S' RNA experiments. Samples of each peak were collected, dried on planchets and counted with a Packard gas flow counter.

Table 2

	Methylated bases (%)	Pseudo-uridylic acid (%)
Transfer RNA	1.5	4.60
'5 S' RNA	0	0.25

The aminoacyl acceptor capacity of the two soluble RNAs was tested *in vivo*. KB cells in exponential growth were labelled with  $^{14}\text{C}$  protein hydrolysate ('Algal') for 5 min. The RNA after deproteinization were chromatographed on an MAK column. The residual radioactivity was localized in the peak of transfer RNA and there was none in the RNA '5 S' peak.

The new fraction of soluble RNA found in the KB or rat liver cells shows a number of properties identical to the RNA '5 S' described by Rosset *et al.*<sup>4</sup>: solubility in M NaCl, molecular weight, behaviour on MAK columns,

linkage on the ribosomes, base composition approaching that of transfer RNA although different, absence of methylated bases and pseudo-uridylic acid, and absence of aminoacyl acceptor capacity.

Elson has also described a '4-5 S' particle, linked with ribosomes, the aminoacyl acceptor properties of which are lower than those of transfer RNA. This can be explained by a simultaneous liberation of a mixture of transfer and '5 S' RNA. Rat liver ribosomes, dialysed under conditions identical to those of Elson, release into the supernatant of centrifugation two ribonucleic fractions the behaviour of which on MAK columns is the same as that of the transfer RNA and the '5 S' RNA (unpublished data).

Comb and Katz<sup>5</sup> have found in *Blastocystis emersonii* a fraction which might be identical with ours. By pulse labelling and chase experiments they have been able to attribute to it the role of a precursor of the transfer RNA. Experiments are in progress to determine the biological role of the fraction we have isolated.

## ROLE OF HISTONES AND OTHER PROTEINS IN GENE CONTROL

By PROF. J. A. V. BUTLER, F.R.S.

Chester Beatty Research Institute, Institute of Cancer Research: Royal Cancer Hospital, London

SINCE the original suggestion of Stedman and Stedman<sup>1</sup> that the basic proteins present in the chromatin of animal tissues (histones) act as gene inhibitors, much effort has been devoted to their characterization and a number of fractionation procedures have been worked out<sup>2</sup> which give rise to proteins of characteristically different compositions. There is some doubt as to how far these fractionations can be continued since most of the fractions obtained still show at least one subsidiary band on starch electrophoresis. It has been suggested that the various fractions obtained may still be complex, so that each contains a large number of distinct proteins of a similar character. However, the evidence available does not support this. When 'finger-prints' are made of tryptic digests of the various fractions the number of peptide 'spots' observed is not greater than is compatible with the very limited degree of heterogeneity seen in the starch electrophoretic pictures<sup>3</sup>. If the histones are responsible for gene repression, we could expect that different tissues would show marked differences in their histone components. A number of investigations have been made on this point<sup>4,5</sup>, and they do not reveal any significant qualitative differences in the histone fractions from diverse animal tissues. A number of substitutions in the amino-acid sequences may be found<sup>6</sup>, but they do not appear to be much more extensive than occur in other proteins from different sources, for example, insulin or haemoglobin, and are not sufficient to change the character of the protein.

Similar changes of gene activity would, of course, occur in this theory if certain histone fractions were lacking in particular tissues. At present few investigations have been made of the relative amounts of different histone fractions present in particular cells, owing to lack of reliable

methods. It can only be said that starch electrophoresis pictures of the whole histone from different animal tissues are remarkably similar<sup>3</sup>. If each gene were associated with a distinct histone, there would have to be some highly specific types of interaction which would be capable of associating each DNA with a particular histone molecule. Johns and Butler<sup>7</sup> found no evidence of specific interactions between histone fractions and different parts of DNA.

On the other hand, the gene inhibitor theory of histones has been supported by experiments *in vitro*<sup>8</sup> which show that histones do inhibit the synthesis of RNA on the DNA template, and that native chromatin can be made to support RNA synthesis to some extent by removing histone (although the removal of the lysine-rich histone F1 has been reported<sup>9</sup> to have no effect) and that active chromatin fractions which are deficient in histone have been obtained<sup>8</sup>.

On the other hand, histones have not been found associated with DNA in bacteria, although complex types of gene regulation occur. It has been demonstrated that the bacterial chromosome may consist of a single continuous circular DNA fibre and that in replication the DNA polymerase moves around the fibre beginning at a specific attachment site<sup>10</sup>. It has been suggested<sup>11</sup> that the DNA polymerase is a double ring which moves down the two strands of the DNA. A single ring of this kind would suffice for the RNA polymerase and it is significant that electron micrographs indicate this shape<sup>12</sup>. Berg *et al.*<sup>13</sup> have described experiments which indicate that while DNA synthesis can only begin at a single attachment site, RNA polymerase action can begin at any point, or at least at a number of points on the circular chromosome.

It has been shown in *B. megaterium* that the RNA polymerase is firmly attached to the DNA<sup>14</sup>, and can only be removed by disrupting the DNA. This is only compatible with Kornberg's observation if there are a number of entry sites at which the RNA polymerase can become attached to one of the strands of the circular chromosome. According to the theory of Jacob and Monod<sup>15</sup> the structural genes, which actually produce messenger RNA, are controlled by regulator genes which normally produce repressor substances, and activation occurs only when the flow of the latter to the operator genes is interrupted. However, no repressor substances have been isolated. The entry sites for the polymerase would naturally be associated with the regulator genes the function of which would be to permit or prevent the attachment of the polymerase to the DNA fibre. Once attached it could be supposed to be able to move down one of the strands of the DNA of the operator gene, presumably determined by an end structure, although the different polarity in the two strands might be sufficient for this purpose.

If such a mechanism is postulated it is evident that the combination of the appropriate substrate with the protein on the regulator gene could produce a conformational change which would 'open the gate' and permit the RNA polymerase to attach itself to the operator genes.

A similar mechanism can be extended to apply to the chromosomes of complex differentiated organisms. It has been suggested by Hotta and Basell<sup>16</sup> that in these also the DNA consists of circular loops, joined together by some form of backbone, possibly also consisting of DNA. As the amount of histone is usually insufficient to cover the whole of the DNA, non-histone proteins, the 'residual proteins', which may well be of a more varied character, are also present. If this is so the ring parts of the chromosome may well be associated with different proteins from the 'backbone', and while the major ring portions would naturally be associated with the histones, the backbone might well be associated with residual proteins and function as regulator genes. As in the bacterial case this would provide more varied proteins than histones provide. As in the bacterial situation they could be sensitive to appropriate substrates or to hormones.

This type of control is indicated by the experiments of Talwar *et al.*<sup>17</sup>, who isolated from rat uterus a protein which by itself was inhibitory and when combined with a specific hormone produced a stimulation of RNA synthesis.

The chief advantage of this hypothesis is that it provides greater opportunities of specific gene control by cell constituents than is provided by histones. The difficulty of explaining how a particular protein is associated with a particular piece of DNA remains. While histones are

bound to DNA almost entirely through ionic bonds, the non-histone proteins which are non-basic and predominantly acidic in character may not be bound in this way. With these proteins there is undoubtedly more scope for specific interactions through hydrogen bonds with the free  $-NH_2$  and  $-OH$  groups of the DNA; but it seems more likely that the regulatory proteins are made on or close to the site to which they must become attached.

This would mean that the regulator genes must code for their own proteins. This would not present any difficulty even if synthesis occurred on ribosomes, since it has been shown (in the bacterial case in any event)<sup>18</sup> that ribosomes are present in close proximity with the genes and are probably required to pull newly formed messenger RNA off the template. This means that the combination of messenger RNA and ribosome could begin to synthesize protein at once, even before the RNA was completely separated from the template, and the attachment of the protein formed to the template would follow. It is interesting to note that Patel and Wang<sup>19</sup> have suggested that 'residual' protein can be formed directly on the DNA template. If confirmed this would get over the difficulty of finding mechanisms to ensure that the regulatory proteins reach their proper sites.

This work was supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the Medical Research Council and the British Empire Cancer Campaign for Research, and by the U.S. Public Health Service research grant CA-03188-08 from the National Cancer Institute.

## FREE AMINO-ACIDS ON HUMAN FINGERS: THE QUESTION OF CONTAMINATION IN MICROANALYSIS

By PROF. J. ORÓ and H. B. SKEWES

Department of Chemistry, University of Houston

FEW quantitative studies using modern techniques have been made concerning the amino-acids present on human skin<sup>1,2</sup>. With the exception of the work of Hamilton<sup>3</sup> we know of no studies which have dealt specifically with the amino-acids on the skin of the fingers. The handling of samples and experimental apparatus usually involves contact with fingers. Even in cases where handling is done by mechanical devices, there is a probability that during the history of a given sample (rock, meteorite, etc.) such a contact has taken place. Since it is possible that contamination by the ninhydrin-positive compounds present on the surface of fingers may affect

the results of amino-acid analyses at the micromolar level, we have made a qualitative and quantitative study of these compounds as they are normally found on human hands and fingers. In this article we report primarily the amino-acids found on the fingertips of seven individuals. The analyses were carried out by ion-exchange column chromatography using the Beckman-Spinco model '120B' automatic amino-acid analyser.

The experimental procedure was as follows. The samples were taken at random with regard to the time of the day and to the age and sex of the individuals. Any foreign particles which might have been present on the

\* This peak contains both proline and citrulline. The value shown was obtained from the absorbance at 440 m $\mu$  to which the citrulline contributes, but not to a large degree. † This peak contains both ornithine and lysine.

surface of the index finger were removed with tissue paper. The tip of the finger was placed in contact with 0.5 ml. citrate buffer, pH 2.2, for 15 sec in a small, clean beaker. Exactly 0.25 ml. of the resulting solution was applied to the chromatographic column for analysis.

Fig. 1 shows the ion exchange chromatograms obtained from seven individuals, identified by the letters at the left of the figure. The chromatograms in the left-hand column (A) correspond to the acidic and neutral amino-acids and those in the right-hand column (B) to the basic amino-acids. Two analyses were made on different days from each of the first three subjects (*S*, *R*, *I*). This was done in order to determine the reproducibility and the possible variation of the results from day to day.

Other related analyses are shown in Fig. 2 (chromatograms 1-5). In order to detect amino-acids which may be present only in trace amounts, the hands of one subject were washed in 100 ml. of distilled water which was then evaporated to dryness at 1 mm Hg pressure and 25° C. The resulting residue was dissolved in 4 ml. citrate buffer, pH 2.2, 1 ml. of which was analysed as before. The results are shown in chromatogram 1. Chromatogram 2 is a blank run showing the results obtained from the analysis of 0.25 ml. of citrate buffer taken from a clean beaker which was handled in the same manner as in the previous analyses. Chromatogram 3 shows the results obtained from a sample taken from a subject's fingertip shortly after the individual had washed his hands with soap and ordinary tap water. Because dust which is present in the air is also a possible source of contamination, a 0.002-g sample was obtained from the top of a high shelf, extracted with citrate buffer and analysed for amino-acids in the usual way. The results are shown in chromatogram 4. A similar sample of dust was refluxed for 18 h in 6 N HCl, evaporated to dryness and dissolved in citrate buffer. This solution was then analysed for amino-acids, and the results appear in chromatogram 5.

The observations can be summarized as follows. The composition of free amino-acids on the surface of human fingers appears to be essentially constant, not only qualitatively but also in terms of their relative abundance. This becomes evident by looking at the chromatograms of Fig. 1. Each chromatogram contains urea, aspartic acid, threonine, serine, glutamic acid, glycine, alanine, isoleucine, leucine, tyrosine, phenylalanine, lysine, ornithine, histidine, and ammonia. In addition, some show smaller amounts of taurine, proline plus citrulline, valine, methionine, arginine, and one or two unidentified compounds.

Table 2. RATIOS OF AMINO-ACID PAIRS

Sample	Ser	Gly	Ser
	Thr	Ala	Ala
<i>S</i> <sub>1</sub>	5.70	1.72	3.68
<i>S</i> <sub>2</sub>	4.45	1.78	2.85
<i>R</i> <sub>1</sub>	7.00	2.20	4.21
<i>R</i> <sub>2</sub>	4.50	2.17	3.00
<i>I</i> <sub>1</sub>	5.90	1.43	3.78
<i>I</i> <sub>2</sub>	6.11	2.27	3.66
<i>N</i>	4.90	2.67	3.84
<i>O</i>	5.80	2.11	3.48
<i>K</i>	5.23	2.58	3.92
<i>U</i>	5.12	2.33	3.41
Average	5.39	2.13	3.58
S.D.	0.77	0.37	0.38

The most impressive similarity between the analyses is the apparent constancy in the relative concentrations of amino-acids. Obvious examples of this are the amino-acids which appear together in pairs such as threonine-serine (peaks 5 and 6), glycine-alanine (peaks 9 and 10), isoleucine-leucine (peaks 13 and 14) and tyrosine-phenylalanine (peaks 15 and 16). Although the similarity of these pairs is most obvious, there is actually a constancy in the relative abundances of most of the other amino-acids as well (for example, serine-alanine). In some cases, however, the concentrations are too low to permit measurements accurate enough for quantitative comparison. This correlation of relative abundances can also be extended to include the basic amino-acids. As an example the ratio between lysine and histidine (peaks 17 and 19) appears to be fairly constant. A cross-correlation between basic amino-acids on one side and neutral and acidic amino-acids on the other is not possible from these data, because the chromatograms in columns A and B of Fig. 1 were not necessarily obtained from the same samples. In order to ascertain how constant the relative abundances are, the amounts of individual components were quantitatively determined (Table 1) and ratios were obtained for the three most significant pairs of amino-acids. These ratios appear in Table 2.

Fig. 1. Chromatograms of amino-acids present on the fingertips of various individuals, *S*, *R*, *I*, *N*, *O*, *K*, and *U*. Column A shows neutral and acidic amino-acids. Column B shows basic amino-acids. (1) Taurine, (2) urea, (3) unidentified, (4) aspartic acid, (5) threonine, (6) serine, (7) glutamic acid, (8) proline plus citrulline, (9) glycine, (10) alanine, (11) valine, (12) methionine, (13) isoleucine, (14) leucine, (15) tyrosine, (16) phenylalanine, (17) lysine plus ornithine (the presence of ornithine was confirmed by Hamilton), (18) unidentified, (19) histidine, (20) ammonia, (21) arginine. The last column shows the amino-acids of ninhydrin-positive compounds present in each sample excluding ammonia.

Fig. 2. Chromatogram 1 is an analysis of the ninhydrin-positive compounds from the hands of an individual. Column A shows neutral and acidic amino-acids. Column B shows basic amino-acids. Chromatogram 2 is a buffer-glassware blank. Chromatogram 3 is an analysis of a sample like those in Fig. 1 except that the subject's hands had been recently washed. Chromatogram 4 is a dust extract analysis. Chromatogram 5 is the analysis of a dust hydrolysate. Peaks are numbered as in Fig. 1. The last column shows the  $\mu$ moles of ninhydrin-positive compounds present in each sample excluding ammonia.

The analysis of the hand-wash sample (chromatogram 1 in Fig. 2) agreed well with the analyses in Fig. 1. In addition, several compounds were observed at lower levels of concentration than the previously mentioned amino-acids. These include cysteic acid, cystine,  $\beta$ -alanine, and about ten unidentified components. The buffer-glassware blank showed complete absence of amino-acids or other ninhydrin-positive compounds with the exception of ammonia. The appearance of ammonia in the chromatograms is difficult to avoid because of its presence in the atmosphere. The analysis of the compounds obtained from the surface of a recently washed fingertip (chromatogram 3) showed a marked decrease in the presence of ninhydrin-positive compounds, with only traces of urea, serine, and glycine appearing in the neutral and acidic analysis and with the basic amino-acid analysis little changed.

The analysis of the dust extract (chromatogram 4, Fig. 2) revealed only traces of urea, serine, and glycine in addition to ammonia. On the other hand, the dust hydrolysate (chromatogram 5) showed most of the protein amino-acids with traces of a few additional compounds. It should be pointed out that cystine and methionine were not observed at the low concentration-levels of this analysis but a significant peak corresponding to cysteic acid was apparent. There appeared to be similarities in the relative abundances of this chromatogram and those of Fig. 1. However, there were definite differences such as (1) higher than usual concentrations of cysteic acid, aspartic acid, glutamic acid and ammonia, and (2) a lower than usual concentration of urea.

The consistency of the relative abundances of the amino-acids present on human fingers is not surprising since it is probably a reflexion of the steady-state concentration of the free amino-acids in epidermal cells. The metabolism of the epidermis of normal subjects would be expected to be basically the same.

The fact that a typical pattern of relative abundance is evident, and that certain amino-acid pairs are so apparent, can act as a guide in detecting contamination in microanalysis of amino-acids. In other words, there is now a 'contamination picture' of sorts for analyses at the micromolar and lower levels, and data that fit such a picture should be scrutinized carefully. In some cases

where only minor contamination is indicated, it may be possible to make the necessary subtractions to obtain more correct analytical data.

A more complete discussion of these results in relation to data obtained from amino-acid analyses of carbonaceous chondrites and other meteorites<sup>4-6</sup> and some synthetic processes<sup>7</sup> will be published elsewhere. At this moment we would like to note the following.

(1) The amino-acid composition of meteorites<sup>4,6</sup> is very similar to that reported here. This is shown by a visual comparison of the chromatograms in Fig. 1 of this paper and the third chromatogram (free amino-acids) in Fig. 1 of reference 6. The ratios for three pairs of amino-acids (Ser-Thr, Gly-Ala, Ser-Ala) from meteorites (Table 6 of reference 5) is given in Table 3. A good agreement with Table 2 can be observed. The larger values for the standard deviations in Table 3 are to be expected on the following grounds: (a) the analytical method used in this case was paper chromatography; (b) some of the samples were hydrolysed in hydrochloric acid; (c) the histories of the samples were different<sup>8</sup>.

Table 3. RATIOS OF AMINO-ACID PAIRS TAKEN FROM METEORITE ANALYSES<sup>5</sup>

(2) From a quantitative point of view, the amino-acid levels in Fig. 1 are of the same order of magnitude (micromolar) as those reported in meteorites<sup>4,6</sup>. Compare, for example, the micromoles of amino-acids per sample given in Fig. 1 of this article with the corresponding values for meteorites given in Fig. 1 of reference 6. A more correct comparison of results would be possible if the values had been reported per sample instead of per gram. Thus, the higher values (527.7  $\mu$ g/g) reported for the Lancé meteorite (Table 6 of reference 5) may in part result from the fact that less than 1 g (0.32 g) of this meteorite was analysed, necessitating a multiplication of the actual amount of amino-acids found by a factor of about 3.

(3) The situation with regard to the sulphur amino-acids appears to be similar in the present analyses and in those of meteorites. These amino-acids are practically absent at low concentration levels<sup>9</sup> and show up in traces or small amounts at higher concentration levels<sup>9</sup>. Therefore, the argument often adduced<sup>4,7</sup> that the absence of sulphur-containing amino-acids is an indication of the absence of contamination cannot any longer be accepted.

(4) Since  $\beta$ -alanine is not normally present in protein hydrolysates, its presence in a given analysis might also be taken as an indication of the absence of contamination. That this is not so is indicated by the fact that small amounts of this compound have been detected in the hand-wash sample (Fig. 2). Additional amounts of  $\beta$ -alanine can conceivably be formed as a result of bacterial decarboxylation of aspartic acid. Indeed, common bacteria and other micro-organisms are known to decarboxylate aspartic acid into  $\beta$ -alanine<sup>10</sup>.  $\beta$ -Alanine is also distributed by the common housefly (Hamilton, private communication).

(5) It should also be pointed out that, depending on the conditions of the analysis, the positions of certain amino-acids on the chromatogram may be sufficiently changed to cause ambiguity in identification (for example, allo-leucine and methionine). With samples other than

protein hydrolysates the identification is further complicated by the possible existence of other ninhydrin-positive compounds with elution times essentially identical to those of protein amino-acids, as shown by Zacharius and Talley<sup>8</sup> and by Hamilton<sup>10</sup>. Therefore, whenever possible, identification by at least two independent methods should be carried out in these cases.

From the data presented here, and from other studies on carbonaceous chondrites<sup>11</sup>, it would appear that the bulk of the free amino-acids found in the analyses of these meteorites are the result of contamination. This would confirm the results obtained by Calvin and Vaughn<sup>12</sup>, Briggs<sup>13</sup>, and Awapara (personal communication), who were unable to detect amino-acids in carbonaceous chondrites. Using a different approach, Hamilton<sup>8</sup> obtained results similar to those presented in this article.

This work was supported in part by a research grant (NSG-257-62) and by a predoctoral research fellowship to

one of us (H. B. S.), from the National Aeronautics and Space Administration. We thank Dr. Hamilton for valuable comments and assistance.

## REVERSAL OF POTENTIAL ACROSS A LIQUID NON-AQUEOUS MEMBRANE WITH REGARD TO MEMBRANE EXCITABILITY

By GIUSEPPE COLACICCO\*

American Standard Research Division, New Brunswick, New Jersey

PREVIOUS reports<sup>1,2</sup> established that the electrical potential of a pentanol membrane was caused by the appearance and disappearance of the head charges of amphipathic molecules at the oil/water interface. It was also established that the sign of the potential was determined by the sign of the head charge at the interface, and the size of the potential decreased with increasing electrolyte concentration and consequent binding of the counter-ions on the head charges.

The rapid change of sign of the electrical potential of nerve membranes is a feature of the action potential, the mechanism of which, however, is not fully understood. As the oil membrane was found<sup>1,2</sup> to produce a spike of obvious biological interest, this article delves further into the mechanism of the events which may cause the change of sign of the potential.

In my early experiments with pentanol membranes<sup>1</sup> I observed a sudden reversal of potential some time after injecting the amphipathic molecules at the oil/water interface. The explanation was: the amphipathic molecules, after migrating from the spreading interface, overturned and showed the head charge at the opposing interface, thus causing the reversal of potential.

While illustrating that first mechanism I wish to show that the reversal of potential can be brought about not necessarily by a real migration of the amphipathic molecules but alternatively and significantly by either or both of two main ways: consecutive appearance of head charges of the same sign (events  $+a$ ,  $-b$  and  $-c$ ,  $+d$  in Fig. 1) at opposing interfaces, and consecutive appearance of head charges of opposite sign at the same interface (events  $+a$ ,  $-c$  and  $-b$ ,  $+d$  in Fig. 1); and in both theory and practice, the entire cycle of events corresponding to resting spike-resting potential can be made to occur and repeat by any adsorption, ion exchange, film penetration, phase inversion and charge inversion mechanism which is able to operate the successive appearance and disappearance of the head charges at the oil/water interface.

The experiments were performed at 25° C in a modification of the 'hanging drop' cell<sup>1,3,4</sup>. Two saturated calomel electrodes connected the lower and upper aqueous compartments at interfaces A and B (Fig. 1) respectively

to the plus and minus poles of a high-impedance electrometer, Keithley model 610A. The oil phase between A and B was *n*-pentanol. Fig. 1 presents a summary of the signs of the changes of potential as related to the signs of the head charges at the interfaces.

In Fig. 2 the potential in mV is plotted versus time over a total period of 50 sec. At about 6 sec, from left to right, sodium decyl sulphate (SDS) was applied on  $10^{-3}$  M potassium chloride at interface A; the potential rose rapidly and then decayed a few mV between 7.5 and 19 sec as the SDS desorbed from interface A. Molecules of SDS migrated through the oil, and on reaching interface

Fig. 1. Signs of potential changes. When potassium chloride concentrations are  $10^{-3}$  M at A and  $10^{-4}$  M at B,  $|b| > |a|$  and  $|d| > |c|$ .

Fig. 2. Oscilloscope (Tektronics 535-A) tracing of a typical reversal of potential across the pentanol membrane. SDS, 200  $\mu$ g in  $10^{-3}$  M aqueous solution, was applied at interface A on  $10^{-3}$  M potassium chloride. Membrane thickness, 3 mm.

\* Department of Biochemistry, Albert Einstein College of Medicine, New York 61, New York.

*B* overturned and acquired the expected orientation; hence, the appearance of the negative head charges at interface *B* caused a negative ( $-120$  mV, from  $75$  to  $-45$ ) change of potential, which is much larger than the positive one at interface *A* primarily because the electrolyte concentration ( $10^{-3}$  M potassium chloride) at *B* is ten-fold as small as at *A*. The resulting picture of the membrane at  $20$  sec is the combination of  $+a$  and  $-b$  of Fig. 1. Analogously, a reversal from negative to positive potential and a final picture of superimposed  $-c$  and  $+d$  of Fig. 1 followed injection of cetyltrimethylammonium bromide (CTAB) at interface *A*.

The rate and extent of recovery of the potential (between  $20$  and  $50$  sec in Fig. 2) varied from system to system. But actually, in every system investigated, rapid return of the potential to the value preceding the reversal was brought about by restoration of the charged interfaces as illustrated later. In line with a previous observation<sup>3</sup>, the time between spreading and reversal was obviously the shorter the thinner the membrane. Migration of the amphipathic molecules through the oil was confirmed with both anionic and cationic surfactants by testing oil samples at the given interface for the given surfactant; and the reversal of potential occurred only when the surfactant reached that interface. As predicted from Fig. 1, no reversal was obtained when the concentration of the electrolyte at the second interface was larger than or equal to that at the spreading interface; for example, after migration of CTAB from  $10^{-3}$  M potassium chloride at *A* to  $10^{-3}$  M potassium chloride at *B* the potential changed only from  $-150$  to  $-70$  mV and not through zero to a positive potential.

Relevant to these studies and Fig. 2 is the drop, though not reversal, of potential observed by Dupeyrat<sup>4</sup> in experiments with a nitrobenzene membrane. When the stream of surfactant (dodecyltrimethylammonium bromide) migrating under a concentration gradient reached interface *B*, where the electrolyte concentration was the same ( $1$  M potassium bromide) as at *A*, the potential suddenly dropped to nearly zero. At variance with Dupeyrat, the concentration or distribution potential is of no avail to account for the sudden drop of potential. Indeed, with the proper electrode<sup>5</sup> in the stream of surfactant (CTAB) I measure a new concentration potential, and yet there is no drop of potential so long as the surfactant does not appear at the opposing interface. Vice versa, injection of the surfactant at the opposing interface causes the sudden drop of potential independently of the bulk concentration of surfactant; and in both cases, as expected, the concentration potential does not change until the migrating surfactant touches the electrode.

Unlike that in Fig. 2, where migration of SDS from *A* to *B* occurred, the same reversal of potential though without migration of SDS was experienced after spreading SDS successively at *A* and *B* at any desired time-interval, in a system equivalent to the consecutive appearance of charges of the same sign at two opposing interfaces. Previously<sup>3</sup>, duplication of the rise and fall of the spike potential was shown when acetylcholine was applied to an oil membrane; the mechanism of the pertinent changes, however, was not fully explained.

In another system, illustrating the successive appearance of charges of opposite sign at the same interface,  $10^{-3}$  M potassium chloride was put on both sides of the pentanol membrane; a reversal of  $+870$  mV from  $-150$  to  $+220$  mV followed injection of  $600$   $\mu$ g of CTAB or SDS consecutively at interface *A* while no change was made at *B*. Apparently, the incoming SDS removed CTAB by penetration and/or adsorption (ion pairing) and produced a negatively charged surface at *A* responsible for a positive potential.

Furthermore, anionic and cationic liquid membranes were prepared by dissolving the surfactant in the oil. In a picture resembling the combination of  $+a$  and  $-b$

of Fig. 1, a solution of  $10^{-3}$  M SDS in amyl alcohol between  $10^{-1}$  M potassium chloride at *A* and  $10^{-3}$  M potassium chloride at *B* produced a stable potential of  $-72$  mV. Sudden reversal of the potential (without migration of surfactant across the membrane) from  $-72$  to  $+70$  mV followed injection of CTAB at interface *B*: removal of SDS and establishment of CTAB at *B* caused the negative potential to vanish and a net positive potential to appear, which is about the combination of  $+a$  and  $+d$  of Fig. 1.

Similar results were repeatedly obtained with a number of organic molecules and with various preparations of cephalin and lecithin contaminated with acidic lipids at the oil/water interface<sup>1</sup>. Conditions leading to the reversal of potential are numerous. A difference in electrolyte concentration across the membrane is not required to produce a potential and a reversal of potential. Injection of different quantities of surfactant at *A* in contact with electrolyte of the same concentration as at *B* (Fig. 1) caused a potential which increased with the concentration of that surfactant, meaning that really the charge density of the surfactant at the interface gives the measure of the potential. The reversal of potential may therefore be brought about by the concerted appearance and disappearance of given quantities of fixed head charges at the interface. That could be made to occur in a number of ways, among which ion exchange in the double layer and alternate admission (appearance and disappearance) of different elements of a mosaic-like structure may be worthy of attention.

The action potential, actually, consists of the sequence of two reversals, that is, from resting to spike and back to resting. Thus far I have described only the first reversal. In all the cases investigated I produced the second reversal by restoration of the surface charge to the state preceding the first reversal. For example, a pentanol membrane containing  $10^{-4}$  M SDS between  $10^{-3}$  M potassium chloride at *A* and  $1$  M potassium chloride at *B* produced a potential of  $+125$  mV. Injection of  $600$   $\mu$ g CTAB at *A* caused a reversal to  $-145$  mV. Thereafter, that same membrane experienced consecutive reversals of potential to  $+125$  and  $-125$  mV six more times (so far as I observed) back and forth following the consecutive injection of the same quantity of SDS and CTAB three times each at interface *A*. No migration of surfactant was involved here; film penetration, adsorption and ion exchange may be surmised; in Nature, that general mechanism of change of the surface charge may be provided by ion exchange and phase and charge inversion mechanisms operating near or within the membrane.

Regardless of the form, be it a real physical migration or overturning of head charges through a fluid structure, or, more likely, be it a mechanism of phenomenological migration (of head charge) associated with the appearance and disappearance of the head charges on the surface of the membrane, the concept of migration of the head charges across the membrane is relevant to the suggestion made by Hodgkin and Huxley<sup>6</sup>. They maintained that only the movement, across the membrane, of species possessing a large charge or dipole moment could account for the observed changes of ionic permeability during the excitation of the nerve membrane. The transport of the electrolyte across the living membrane may therefore just coincide with, or follow, the development of the electrical potential by the charged interfaces rather than by itself be the immediate cause of the potential.

Inasmuch as no flux of electrolyte was required for the dramatic changes of potential observed across the thick ( $0.3$ – $10$  cm) oil layer, the oil membrane exemplifies for the first time the unequivocal separation between potential of the fixed head charges and potential of the electrolyte. It is not known if and to what extent this new element of non-concentration and non-diffusion potential of the oil membrane could be operating in biological

membranes. Simulation of a change of surface charge by the alternate admission of anionic and cationic solid exchange membranes ('Amphion A-80 and C-89'), in place of the oil membrane in Fig. 1, also caused the typical reversal of potential where there was no change of electrolyte concentration; a fundamental ingredient in the mechanism of resting and action potentials may therefore have to be sought directly in the charged

components of the membrane rather than in the electrolyte bathing the membrane.

## METAL-CATALYSED DECOMPOSITION OF $\alpha$ -HYDROXYPOLYCARBOXYLIC ACIDS

By DR. S. P. DATTA, DR. A. K. GRZYBOWSKI and DR. S. S. TATE

Department of Biochemistry, University College, London

IN connexion with work on the reaction catalysed by the enzyme citrate lyase (EC 4.1.3.6):

we have made a detailed examination of the magnesium and manganese complexes of citrate, these two metal ions being activators of this enzyme. The magnesium complexes were straightforward<sup>1</sup>, but unusual results were obtained for the manganese complexes.

Patnaik and Pani showed that, in the presence of manganese (II)<sup>2</sup>, cobalt (II)<sup>3</sup>, zinc<sup>4</sup>, and nickel<sup>4</sup>, four protons ionized from citric acid below pHs near 10, and Warner and Weber<sup>5</sup> obtained similar results in the presence of copper (II) and iron (III). The extra ionization in the presence of manganese was also observed by Shnarevich<sup>6</sup>.

From potentiometric titration of citric acid in the presence of manganese chloride we have confirmed that one extra proton is liberated below pH 10 from citric acid per metal atom present. Thus from 1:1 citric acid:MnCl<sub>2</sub> mixtures four protons were liberated per citric acid molecule, while from 2:1 citric acid:MnCl<sub>2</sub> mixtures 3.5 protons per citric acid molecule were titrated (Fig. 1). However, we observed that in the region of the fourth ionization (pH 7-10) the pH, which rose rapidly on addition of alkali, fell slowly to an equilibrium value. This observation suggests that a process other than a simple ionization occurs. Attempts to calculate the acid dissociation constant of the MnHCit<sup>-</sup> complex from the equilibrium pH values failed to yield a constant value.

Fig. 1. Titration of citric acid (0.18 mmole) with NaOH in the presence of MnCl<sub>2</sub> (0.06 mmole) and back titration with HCl. O, Forward titration with NaOH; x, back titration with HCl.

Fig. 2. Time variation of the optical density of a solution containing 0.0464 mmole trisodium citrate + 0.006 mmole MnCl<sub>2</sub> and excess alkali in a total volume of about 3 ml. The times at which the scan passed 250 mμm were: curve 1, 90 s; curve 2, 215 s; curve 3, 340 s; curve 4, 465 s, and curve 5, 590 s.

Fig. 1 shows a titration curve of a 2:1 citric acid:MnCl<sub>2</sub> mixture, sodium hydroxide solution was the titrant in the forward direction and hydrochloric acid solution in the back titration. The clear difference between the forward and the back titration curves shows that a change had taken place in the acid-base system.

The occurrence of another process was confirmed by spectrophotometric measurements. Fig. 2 shows the change with time of the ultra-violet absorption of a solution of trisodium citrate (adjusted to pH 11 with alkali) after the addition of MnCl<sub>2</sub>. A new species with an absorption band near 230 mμm was evidently formed. There was no visible sign of manganese hydroxide precipitation; this is not surprising since the ligand:metal ratio was > 9.

It appeared possible that the unknown process might be the non-enzymatic cleavage of citrate to oxaloacetate and acetate. Tests on alkaline citrate-manganese solutions with 2,4-dinitrophenylhydrazine showed that a keto-acid was present<sup>7</sup>. However, attempts to demonstrate that the keto-compound was indeed oxaloacetate, by its reduction to malate with NADH in the presence of malate dehydrogenase, were unsuccessful. The oxidative decarboxylation of citrate tetra-anion could give acetone dicarboxylate according to the reaction:

The keto-acid dinitrophenylhydrazones from the reaction mixture were therefore extracted by McArdle's method<sup>6</sup> and examined by paper chromatography using the solvent system of El Hawary and Thompson<sup>7</sup>. The chromatogram showed spots corresponding to the dinitrophenylhydrazones of both acetone dicarboxylic acid and acetoacetic acid. The latter could have been formed by the decarboxylation of the former. The results were, however, not always reproducible, possibly because in some circumstances the acetone dicarboxylic acid was completely decarboxylated to acetone the dinitrophenylhydrazone of which is not extracted by the method used.

To test whether this is a general reaction of  $\alpha$ -hydroxy-polycarboxylic acids with transition metal ions, we titrated isocitric, citramalic, malic, isomalic and tartronic acids in the presence of  $Mn^{2+}$ ,  $Co^{2+}$  and  $Cu^{2+}$ . The ionization of an extra proton was unambiguously demonstrated in the presence of all these metal ions for isocitric, isomalic and tartronic acids, whereas with citramalic and malic acids the extra ionization was only seen definitely in the presence of  $Cu^{2+}$  ions. With these last two acids and  $Mn^{2+}$  or  $Co^{2+}$  ions the evidence was less definite, possibly due to the low stability of the complexes. Malonic, succinic and tricarballic acids did not give rise to extra ionizations in the presence of any of these metal ions, which suggests that the source of the extra proton is the hydroxyl group and not a co-ordinated water molecule. With all these hydroxy-acids, titrated in the presence of one of these metal ions, keto-acids were detected in the solutions after titration of the extra proton. By analogy with citric acid, the following conversions would be expected:

Fig. 3 shows the increase with pH in the amount of keto-acid (presumably glyoxylate) formed in solutions containing tartronate and  $MnCl_2$  in a 5:1 ligand:metal ratio, estimated as the 2,4-dinitrophenylhydrazone<sup>7</sup>. The enhancement of keto-acid formation by the passage of oxygen through the solution and its suppression when oxygen was excluded by passing oxygen-free nitrogen (nitrogen bubbled through Fieser's solution) through the

Fig. 3 pH-dependence of keto-acid (glyoxylate) formation from tartronate in the presence of  $MnCl_2$  at 25°. ● Each solution contained 1 ml. 0.05 M tartronic acid + 1 ml. 0.01 M  $MnCl_2$  + 5 ml. water. The pH was quickly brought to the required value with 0.108 M NaOH and maintained there for 15 min. At this time 5 ml. of the mixture was pipetted into 1 ml. M. HCl and the keto-acid estimated by the method of Friedmann and Haugen (ref. 7).  $CO_2$ -free nitrogen was passed through the solution during incubation; Δ, same conditions except that oxygen was rigorously excluded; □, same conditions except that oxygen was passed through the solution during incubation.

Fig. 4. Confirmation of the formation of pyruvate from isomalate in the presence of  $MnCl_2$ . The reaction mixture, volume 8.0 ml., initially contained 2.5 ml. 0.03 M  $KH_2PO_4$  (adjusted to pH 7.4 with NaOH) + 0.1 ml. of extract prepared as described in the text + approximately 0.5  $\mu$ moles NADH. Approximately 1.2 units of lactate dehydrogenase (Boehringer) were added as shown.

solution are also indicated. The formation of pyruvate and glyoxylate from isomalate and tartronate, respectively, was confirmed by paper chromatography of the dinitrophenylhydrazones.

The formation of pyruvate from isomalate in the presence of  $Mn^{2+}$  ions was further confirmed as follows. A mixture of 1 ml. 0.1 M isomalic acid + 5 ml. water + 0.8 ml. 0.1 M  $MnCl_2$  was adjusted to pH  $\approx$  10 with 0.98 M NaOH, incubated for 15 min, acidified, and extracted with ether. The ethereal layer was re-extracted with about 2 ml. of 0.03 M  $KH_2PO_4$ , adjusted to pH 7.4 with sodium hydroxide solution. This extract was used to oxidize NADH in the presence of lactate dehydrogenase as is shown in Fig. 4, the reaction being followed by the fall in optical density at 340 m $\mu$ . Fig. 4 shows that 0.1 ml. of the extract caused the oxidation of only a part of the NADH present and further addition of 0.05 ml. of the extract caused the oxidation of a further amount of NADH. Isomalate (50  $\mu$ moles) did not oxidize NADH in the presence of lactate dehydrogenase.

Further experiments with alkaline isomalate solutions containing  $Fe^{2+}$ ,  $Fe^{3+}$ ,  $Zn^{2+}$  and  $Ni^{2+}$  ions showed that keto-acid was formed in the presence of  $Fe^{2+}$  and  $Fe^{3+}$ , but  $Zn^{2+}$  and  $Ni^{2+}$  proved inactive in this respect.

It is difficult to visualize the oxidation of  $\alpha$ -hydroxy-polycarboxylic acids in the presence of reducing species such as  $Mn^{2+}$ . The experiments shown in Fig. 3 indicate that oxygen may be involved. The following reactions may therefore take place:

and

The sum of reactions (2) and (3) is:

assuming that  $\text{HCO}_3^-$  reacts with  $\text{OH}^-$  to form  $\text{CO}_3^{2-}$  and water.

When oxygen was rigorously excluded from the solution (Fig. 3), the fall in pH with time in the region of the extra ionization was still observed but no keto acid formation could be detected. This would indicate that reactions (2)–(4) here are not the only ones which occur in this system.

We thank the Royal Society for a grant to purchase some of the apparatus used, and the Medical Research

Council for financial support for one of us (S. S. T.). Miss Anna Straker helped in preparing the manuscript and figures.

## WEBER RATIO IN GUSTATORY CHEMORECEPTION; AN INDICATOR OF SYSTEMIC (DRUG) REACTIVITY

By PROF. ROLAND FISCHER, FRANCES GRIFFIN, ROBERT C. ARCHER, STEPHEN C. ZINSMEISTER  
and PROF. PHILIP S. JASTRAM

Research Division, Department of Psychiatry, College of Medicine and Department of Physics,  
Ohio State University, Columbus

THE exponential nature of the perceptual process has been amply documented through the years from Fechner's discovery in 1860 to Stevens's<sup>1</sup> proposed modification of it in 1961. In order to propagate quantitative information, the nerve cells cannot increase the intensity of the impulses: they only increase their frequency. Katz<sup>2</sup> and Adrian<sup>3</sup> found that this frequency is proportional to the logarithm of the 'intensity' of the stimulus. It appears now that Stevens's power law describes sensation magnitude before adaptation to a test stimulus, whereas the Fechnerian discriminability law describes it after adaptation<sup>4</sup>.

### Re-examination of Data and Models

Let us examine the logarithmic function implied in the Weber-Fechner law in one sense modality: gustatory chemoreception. We focus specifically on the data of Lemberger<sup>5</sup> since they have been repeatedly used to support models and mechanisms in gustatory chemoreception.

Lemberger obtained 40 successive 'just-noticeable differences' (jnd) for sodium saccharinate. Beidler<sup>6</sup> plotted these data according to his "fundamental taste equation", an adaptation of the Langmuir adsorption isotherm, with the assumption that "each jnd is proportional to an equal increment of neural activity"; specifically  $C/R$  was plotted against  $C$ , where  $C$  is the concentration and  $R$  is the number of the successive 'just-noticeable differences'. A closer inspection reveals that the linear relationship applies for the concentration range between the 11th and the 36th jnd alone.

Duncan<sup>7</sup> also re-examined Lemberger's data for sodium saccharinate and re-plotted her first 22 jnd's; he found a pronounced curvature in the range of the first nine jnd's instead of a linear relationship implied by Beidler. It is apparent, therefore, that Lemberger's data in this lower range do not fit the fundamental taste equation nor is there a linear relationship beyond the 36th jnd.

In summary, Lemberger, Beidler and Duncan used the same set of data to fit their three different models. (1) Lemberger<sup>5</sup> (p. 308) showed that the taste response closely follows a logarithmic curve deviating from the Fechner law only in the lower and higher ranges. (2) Beidler<sup>6</sup> used Lemberger's data to fit his fundamental taste equation, whereas (3) Duncan<sup>7</sup> used them for the demonstration of a "hyperbolic rather than a logarithmic relationship between the magnitude of the response and the stimulus intensity".

It was of interest to us to plot Lemberger's data without trying to fit them to a model. Such an 'assumptionless'

plot of the 40 successive jnd's of Lemberger for sodium saccharinate relates the concentrations of the lower limits on the abscissa to their corresponding upper limits on the ordinate. Our plot (Fig. 1) illustrates a closely linear relationship between the lower and upper limits of successive jnd's within the range spanning jnd 7 to jnd 38. Our 'assumptionless' plot apparently illustrates a non-linear relationship for the first 6 successive jnd's followed by a linear relationship to the 38th jnd—just 2 jnd's from the maximum response.

We may define a jnd in taste as a 'signal' and its lower concentration limit 'noise' as Barlow<sup>8</sup> did for light stimuli. The well-known Weber ratio or signal/noise ratio<sup>9</sup> in these terms is independent of the units of measurement and thus is a dimensionless number. (Instead of equal increments of neural activity, we prefer to define Weber ratios as 'dimensionless numbers', that is, 'similarity criteria' or 'dimensionless ratios' rather than 'units'.) We plotted the size of each successive jnd,  $\Delta S$ , of Lemberger against the concentration of its lower limits,  $S$ ; the Weber ratio,  $\Delta S/S$ , is illustrated in Fig. 2 on a log-log scale. A distinctly non-linear relationship exists for the first six successive jnd's resembling a 'half moon'; a linear one for the range between the 7th and the 36th jnd revealing the prevalence of a steady signal/noise ratio. The non-linearity of the 'half-moon' portion of the curve, that is, the first six jnd's with a lack of steady signal/noise ratio, does not support models based on the Langmuir adsorption isotherm.

We proceeded to calculate the mean Weber ratio for sodium saccharinate—between the 7th and the 36th jnd—and found it to be  $11.02 \pm 0.08$  per cent (S.E.); the corresponding value for sucrose, again using Lemberger's data, between the 7th and the 22nd jnd, that is, the linear portion of the curve, was larger, namely,  $15.64 \pm 0.14$  per cent (S.E.).

The obvious hypothesis suggested itself: the larger Weber ratio for sucrose may be due mainly to its being a less-effective competitor than sodium saccharinate for receptor sites in the presence of tap-water electrolytes. Our subsequent experiments, however, did not substantiate such a hypothesis.

### A Comparison of Methodologies In Jnd Determination

Lemberger's criteria of taste testing are fully described in her paper<sup>5</sup>. The main features of her procedure are recapitulated only to enable us to compare them with ours. Specifically, she was her own subject, used tap-water as a rinse, a temperature of about 19° C for solutions and

Fig. 1. Relation between upper (ordinate) and lower concentration limits (abscissa) of successive just-noticeable differences (jnd) in the taste sensation of sodium saccharinate calculated from Lemberger's data (ref. 5, Table 8). The plot of the first 18 jnd's is magnified in the upper left corner for better visibility.

rinses and a tediously slow sorting procedure—with one jnd determination apparently requiring 2–3 days. Lemberger's limits of accuracy for determining a jnd were based on obtaining at least 75 per cent differentiations.

Our modification of the Harris-Kalmus threshold determination procedure was adapted to just-noticeable taste difference testing and involved the use of distilled water for solutions as well as for rinsing between cups and the final 100 per cent correct sorting technique<sup>11</sup>. The following adaptations were introduced in order to make the method, originally designed for the determination of taste thresholds, suitable for jnd measurements. The original procedure involved taste thresholds, represented by solution numbers each of which corresponded to a concentration the double of the previous concentration. In our adaptation: (1) a threshold—the baseline or lower limit of the first jnd—was determined to a resolution of 1 per cent of a whole solution number; the same was true during subsequent jnd determinations, that is, also for testing the upper limit of each jnd (the standard errors of our procedure are to be found in Tables 1, 2 and 3); (2) during the determination of the upper concentration limit of each jnd we used—instead of distilled water placebo—the upper concentration limit of the preceding jnd; (3) the temperatures of all solutions and rinses were thermostatically controlled to either 19 or 22  $\pm 0.1^\circ\text{C}$ , the former corresponding to Lemberger's experimental conditions and the latter to our standard laboratory procedure. Our

subjects were trained, that is, 'learned', laboratory personnel constantly exposed for from 1 to more than 2 years to taste testing practice, and one additional subject who was a novice in taste testing. Lemberger's procedure required a criterion of 75 per cent correct sorting against our requirement of 100 per cent; this difference, however, cannot account for more than 0.5 per cent change in the values of the concentration limits for jnd's; (4) the concentrations are expressed linearly as molarities in Tables 1, 2 and 3, whereas, in fact, the resolutions of the upper and lower limits of the jnd's are determined to 1 per cent of a concentration corresponding to the next higher solution number, a member of an exponential series with a base of 2 (ref. 12).

The first eleven successive jnd's are well within the linear portion of a Weber ratio plot as evidenced by the fact that even up to the fifteenth jnd the plot remains linear. Therefore, we restricted ourselves to the determination of the first eleven successive jnd's.

#### Attempts to reproduce Lemberger's Data

Our attempts to reproduce Lemberger's data, specifically the 'half-moon' part of the  $\Delta S/S$  plot (Fig. 2), were unsuccessful. We set out, therefore, to determine the influence of each variable in the procedure on the outcome of the experimental data to account for our inability to reproduce her data. We studied the influence of three main variables possibly involved in the initial 'half-moon' feature of Fig. 2, namely, temperature, type of rinse water and chemical structure of the compound.

The importance of the difference in temperature of the compound solutions, rinses and placebo was determined by comparing Weber ratios obtained at a temperature of 19 $^\circ\text{C}$  (as used by Lemberger) and at a temperature of 22 $^\circ\text{C}$ . Table 1 presents the first eleven jnd's for sodium saccharinate obtained with solutions, rinses and placebo at 19 $^\circ\text{C}$  and Table 2 presents jnd's obtained at 22 $^\circ\text{C}$ . Temperature was found to be of no significance since the mean Weber ratio at 19 $^\circ\text{C}$  of  $33.03 \pm 2.6$  per cent (distilled water) and  $33.23 \pm 7.52$  per cent (tap-water), com-

Mean Weber ratio: 32.71 $\pm$ 1.79 per cent (S.E.)					Mean Weber ratio: 32.71 $\pm$ 5.58 per cent (S.E.)			

pared with the mean Weber ratio at 22° C of 32.71 = 1.79 per cent (distilled water) and 32.71  $\pm$  5.58 per cent (tap-water), are clearly of the same order of magnitude.

Secondly, the influence of the type of rinse water was examined. Both sodium saccharinate and sucrose jnd's were determined with tap-water and distilled water rinses (Tables 1, 2 and 3). No significant differences were found in mean Weber ratios for sodium saccharinate at 19° C, 33.23  $\pm$  2.6 per cent (distilled water) and 33.23  $\pm$  7.52 per cent (tap-water); for sodium saccharinate at 22° C, 32.71  $\pm$  1.79 per cent (distilled water) and 32.71  $\pm$  5.58 per cent (tap-water); for sucrose at 22° C, 41.06  $\pm$  1.02 per cent (distilled water) and 40.48  $\pm$  1.14 per cent (tap-water).

Our investigation of the third variable, the possible influence of the chemical structure of a compound on the mean Weber ratio, was a comparison of the size of mean Weber ratios for sucrose (an un-ionized compound) with the data for sodium saccharinate (an ionized compound) at 22° C for the two-rinse water conditions (Tables 2 and 3).

A survey of our experimental data allows us to state the following: (1) A 3° C difference in temperature has no effect on the mean Weber ratios for sodium saccharinate other than to increase slightly the standard error at the lower temperature. (2) The type of rinse water has no influence on the mean Weber ratios for sodium saccharinate; however, the effect of a tap-water rinse is to increase the standard error (see Tables 1 and 2); (3) the tap-water rinse has no effect on the mean Weber ratios for either of the two compounds at 22° C; however, the standard error with tap-water rinse for the ionized compound (sodium saccharinate) is increased more than for sucrose, the un-ionized compound (see Tables 2 and 3).

In spite of controlling temperature and type of rinse water, we are unable to reproduce the initial curvilinear portion of Lemberger's sodium saccharinate curve ('half-moon') nor to establish a single factor to account for the lack of this initial curvilinear portion (from the first to the sixth jnd) in our data. Nor can we find any explanation for the 2.5–3 times smaller size of Lemberger's

mean Weber ratios for sucrose and sodium saccharinate, respectively, within the linear range of her data (from the 7th to the 36th jnd) compared with our mean Weber ratios.

Further differences between Lemberger's and our methodologies, however, may account for our inability to reproduce the curvilinear 'half-moon' (the range between the first and sixth jnd) and for the fact that her Weber ratios were 2.5–3 times smaller than ours:

(1) Our average daily performance consisted of determining up to 20 jnd's; whereas Lemberger, according to her description, can be assumed to have taken 2–3 days for the determination of one jnd.

(2) Our subject, as already mentioned, was 'learned', that is, his threshold for quinine due to conditions of well-defined practice suddenly decreased three thresholds in solution numbers, that is, eight-fold from the point of view of concentration<sup>18</sup> before this experimentation (each successive solution number represents a doubling concentration). We can define his taste sensitivity prior to learning: taste threshold for quinine in solution numbers equals 3, whereas that for 6- $\pi$ -propylthiouracil (PROP) equals solution number 6. The sucrose threshold of our subject was solution number 15, quite similar to that of Lemberger, whose threshold 16, expressed in our solution numbers, corresponds to a concentration of  $2.4 \times 10^{-4}$  M. Lemberger could not have been a 'learned' subject before her experimentation since, according to our experience, learning is apparently restricted to taste practice with quinine under defined conditions and it is not known whether learning can be achieved by tasting sodium saccharinate under Lemberger's experimental conditions. We also attempted to reproduce Lemberger's data with an 'unlearned' subject also slow in taste testing, who, under our experimental conditions, displayed from 25 to 100 per cent variation in the size of his first jnd for sodium saccharinate. We do not know whether the extent of variability is a characteristic of unlearned subjects or an individual characteristic of this 'slow' subject.

Although Lemberger repeated the determination of each jnd until the standard error was minimal for it, she

Table 3. UPPER AND LOWER LIMITS AND THEIR CONCENTRATION DIFFERENCES OF THE FIRST 11 SUCCESSIVE JND'S EXPRESSED IN MOLARITY WITH CORRESPONDING WEBER RATIOS AS A PERCENTAGE FOR SUCROSE AT 22° C USING DISTILLED WATER OR TAP-WATER RINSES

did not repeat the whole procedure of successive jnd determinations. We are unable, therefore, to calculate her standard error for reproducing the whole curve or to compare her data with that of our 'unlearned' subject.

The relation between the magnitude of stimulation and sensory response is tabulated for the six sets of data in Tables 1, 2 and 3, of which the latter deserves special attention. With arithmetically increasing concentration limits there is a corresponding geometrical increase in magnitude of jnd. This increase, evident in Table 3, is progressing in a quantum fashion, whereby each quantal unit is exactly the double of the previous one. The sinusoidal fluctuation in the magnitude of the first eleven Weber ratios (see Table 3), alternating with troughs of 38.46 per cent and peaks of 44.44 per cent, correspond to a period of 30 min.

In summary, a graphic and experimental re-examination of Lemberger's data led us to the elucidation of methodological factors in jnd determination influencing the size of a dimensionless ratio, the Weber ratio. For both sodium saccharinate and sucrose, we found a straight line plot for the Weber ratios with rhythmical doubling of concentration limits and sinusoidal fluctuations in the Weber ratios.

#### Size of a Weber Ratio as an Indicator of Systemic Reactivity

Recently it was found that a statistically significant relationship exists (within a group of 48 acutely ill female schizophrenic patients) between extrapyramidal side effects induced by a low cumulative dose of trifluoperazine and taste sensitivity. Side effects displayed in response to higher trifluoperazine dosage were more likely to occur in taste-insensitive patients<sup>12</sup>.

We wondered whether the size of a Weber ratio, instead of taste threshold, would also be related to systemic (drug) reactivity. Our pilot experiments indicate that trifluoperazine-induced tranquillization increases, whereas 'Piloocybin'-induced (central) sympathetic stimulation decreases, the size of an individual's Weber ratio for sodium saccharinate (see Table 4).

Our sample consisted of 12 acutely ill mental patients, 7 of whom were on high and 5 on low trifluoperazine medication with a male to female ratio 1:1; 7 healthy volunteers of whom 5 were under the influence of 'Piloocybin' and a week later without any drug. 'Piloocybin' was chosen because it produces a transient state of central sympathetic stimulation<sup>14</sup>, thus contrasting the tranquillizing effect of trifluoperazine and enabling us to compare the size of Weber ratios under these two extreme systemic conditions.

We used sodium saccharinate at 22° C with distilled water rinses when determining a jnd approximately two thresholds above the sodium saccharinate threshold of a patient but still well within the linear portion of the Weber ratio plot.

Even individual variations in reactivity to trifluoperazine or to 'Piloocybin' seem to be mirrored in the size

of the Weber ratio. To give a specific example: a taste-sensitive volunteer reacted to 12.5 mg 'Piloocybin' more intensely than another less taste-sensitive subject to 15 mg of the same drug; their Weber ratios at the peak of drug experience were 29 and 39 per cent respectively.

One set of data requires comment, namely, the approximately 20 per cent higher mean Weber ratio of the 7 healthy volunteers in Table 4 (48.9  $\pm$  1.8 per cent) as compared with the size of the mean Weber ratio for sodium saccharinate in Table 2 (32.71  $\pm$  1.79 per cent). The difference may be accounted for by our observation that continuous taste practice diminished the size of the Weber ratio of our subject in Table 2, whereas the 7 volunteers in Table 4 were not previously exposed to such practice. The nearly identical size of the Weber ratio (48.9  $\pm$  1.8 per cent) in our 7 volunteers may be accounted for by one factor: the sodium saccharinate baseline used in all 7 subjects was identical, namely,  $9.38 \times 10^{-3}$  M.

Table 4. RELATION BETWEEN DEGREE OF TRANQUILLIZATION OR SYMPATHETIC STIMULATION, THAT IS, SYSTEMIC (DRUG) REACTIVITY AND THE SIZE OF THE WEBER RATIO FOR SODIUM SACCHARINATE AT 22° C WITH DISTILLED WATER RINSES

Subjects	Mean Weber ratio for sodium saccharinate at 22° C
(1) Patients on a high daily dose of trifluoperazine (30-60 mg). <i>N</i> = 5, 25-40 years of age	21.7 $\pm$ 9 per cent ( <i>S.E.</i> )
(2) Patients on a low daily dose of trifluoperazine (5-20 mg). <i>N</i> = 7, 25-40 years of age	18.2 $\pm$ 13 per cent ( <i>S.E.</i> )
(3) Healthy volunteers without any drug. <i>N</i> = 7, 21-28 years of age	48.9 $\pm$ 1.8 per cent ( <i>S.E.</i> )
(4) Healthy volunteers, 100 min after the ingestion of 10-15 mg of 'Piloocybin', same subjects as (3). <i>N</i> = 5, 21-28 years of age	34 $\pm$ 2.7 per cent ( <i>S.E.</i> )

\* Only subjects previously exposed to 'Piloocybin' were included to eliminate effects related to 'novelty of experience'.

There are two other factors which may influence the size of a Weber ratio, namely, taste sensitivity and sex. Sensitive tasters have smaller Weber ratios than insensitive tasters; women are, under otherwise identical conditions, more sensitive tasters than men<sup>15</sup>. That excitation diminishes the size of the Weber ratio should not be surprising in view of the data of Kimura<sup>16</sup> and Chernotaki<sup>17</sup>. The latter author found that systemic sympathetic stimulation enhances afferent activity recorded from the glossopharyngeal nerve during application of gustatory stimuli to a frog's tongue. This article also offers an explanation for the sympathetic enhancement of peripheral gustatory activity noted by Kimura in the rat.

We have dealt with methodological and systemic factors related to the Weber ratio in gustatory chemoreception. The constancy within limits of this dimensionless ratio reminds us that we live in a world in which the absolute magnitudes of stimuli go unperceived, a perceptually compressed but "the best of all possible worlds".

The work was supported by U.S. Public Health Service National Institutes of Health, general research support grants administered by the Ohio State University College of

Medicine. We thank the following for discussions, assistance and interest: Dr. J. Gander, Dr. R. Kaelbling, Dr. W. Knopp, Miss B. Mayers, Dr. B. Passamaniok, Miss M. Rockey, Dr. J. Sandberg and Dr. A. Sollberger (Cleveland). We also thank Dr. R. Bircher and Dr. L. B. Achor, Sandoz Pharmaceuticals, Hanover, N.J., for providing us with samples of 'Pilocybin'.

## IMPORTANCE OF MEMBRANES IN PROTEIN BIOSYNTHESIS

By DR. RICHARD W. HENDLER

Laboratory of Biochemistry, Section on Cellular Physiology; National Heart Institute; National Institutes of Health; Bethesda, Maryland

THREE years ago, on the basis of a wide variety of observations reported in the literature from this and other laboratories, a general model for protein synthesis was proposed which suggested that ribosomes are membrane-associated when they carry out their synthetic activities in the living cell<sup>1</sup>. Since that time many new investigations bearing on the validity of such a functional cytological relationship have appeared. Since, at the moment, these important and related papers have not been considered as a unit, it seemed of distinct value to assemble the information so that a clear picture could be drawn of the existing evidence. Although many earlier reports demonstrated that membrane preparations, obtained principally from bacteria, were capable of efficient amino-acid incorporation into protein, the question of whether or not this represented a different mode of incorporation than the more usual free ribosome mediated systems was not amply considered. Furthermore, some systems actively studied, notably *E. coli*, were capable of efficient amino-acid incorporation even though an intracytoplasmic membrane system does not appear to be present and the ribosomes are considered to exist free in the cytoplasm. For the generality of the proposed ribosome-membrane model to extend to such systems as *E. coli*, the possibility was considered that a certain proportion of the ribosomes of *E. coli* were attached to the plasma membrane at any time. These attached ribosomes would be responsible for protein synthesis in the intact cell and due to a lability of their linkage to the membrane would be dissociated by the forces used to break the cell and afterwards would appear as free ribosomes.

In a series of papers, Hendler and Tani presented evidence that the foregoing description does apply to *E. coli* and that the generality of the membrane-ribosome structure for protein synthesis is not compromised by the finding of high amounts of incorporated amino-acids in free ribosome fractions<sup>2-4</sup>.

In several investigations dating from 1958, the group at the Chester Beatty Institute, including Drs. Butler, Hunter, Godson, Crathorn, and Goodall, examined the site of amino-acid incorporation in *B. megaterium*<sup>5</sup>. They showed that the membrane represented the major site of incorporation, that an appreciable fraction of the cellular RNA sedimented with and was held by the membrane, and that ribosomal particles could be released from the membrane by washing with buffers of low ionic strength. Schlessinger recently re-examined this system and confirmed that an appreciable fraction of the total RNA was bound to membranes (more than 50 per cent<sup>6</sup>). Most of this RNA was released from the membranes by lowering

the magnesium concentration from  $10^{-3}$  M to 0. Similarly, 0.2 per cent DOC or subsequent incubation alone was capable of releasing the bound RNA. The RNA released by DOC treatment sedimented in a sucrose gradient principally as polysomes of 4 or more ribosomes. The isolated membranes were capable of incorporating up to 6 times more amino-acid into protein per unit weight of RNA than the ribosome-polysome mixture obtained from a crude extract. Schlessinger pointed out that there was no direct evidence that the polysomes found in the DOC extracts of membrane were present in the membranes as polysomes. In yeast, a membrane-ribosome fraction was described which could incorporate sulphur-35 into stable peptide linkage 5-7½ times faster than free ribosomal particles on a per unit RNA basis<sup>7</sup>.

Moore and Umbreit, in a preliminary communication<sup>8</sup>, reported that in *S. fecalis*, when a washed membrane fraction and a ribosomal fraction were compared, it was found that the membrane-bound ribosomes were about 5-fold more effective than cytoplasmic ribosomes for the incorporation of radioactive amino-acids. This work has continued and Moore and Umbreit have demonstrated that the incorporation of amino-acids in the free ribosome fraction is proportional to their phospholipid concentration. Phospholipid is found only in membranes of *S. fecalis* and is absent from cell walls and cytoplasm. Consequently, these authors conclude that the results indicate a membrane constituent to be the limiting factor in protein synthesis in this system even for the 'free' ribosome fraction<sup>9</sup>.

The localization of ribosomes at membrane sites is further demonstrated by studies involving the incorporation of labelled precursors into RNA in *E. coli*<sup>10</sup> and *Streptococcus fecalis*<sup>11</sup>. In HeLa cells infected with polio virus, it has been shown that the polio-specific polysomes are also membrane-attached<sup>12</sup>. Another study having a possible bearing on this question is that of Neu and Heppel<sup>13</sup>. They found that during the formation of EDTA-lysozyme spheroplasts of *E. coli*, all the latent ribonuclease activity was released from the unlysed cells.  $\beta$ -Galactosidase was not so released, but could be obtained after lysis. If, as is commonly thought, the latent RNase is a part of the *E. coli* ribosome, then this investigation would be consistent with a membrane localization of the ribosomes. Another alternative considered by these authors is that the ribonuclease may actually not be part of the ribosome, but could exist free in a pericytoplasmic compartment.

The sensitivity of micro-organisms to antibiotics also points to a functional association of membranes and

ribosomes. In an investigation of the early sequence of events following the addition of streptomycin to growing cultures of *E. coli*, Dubin *et al.* have demonstrated that loss of membrane integrity and impairment of protein synthesis appear to be related events<sup>13</sup>. More recent work has fixed the site of ribosome damage at the 30S component of the ribosomes<sup>14,15</sup>. Nomura, in a recent investigation of the mechanism of killing action of antibiotic colicines, has also presented evidence in favour of a functional co-ordination of macromolecular synthesis and cell membranes<sup>16</sup>. Thus, several of the colicines inhibit either together or separately the processes of RNA and protein synthesis, oxidative phosphorylation, and maintenance of DNA. The addition of trypsin reverses the action of the colicines. Since the trypsin does not penetrate the bacteria, the colicines presumably act at the cell surface. Nomura discussed the possibility that reactions involved in macromolecular synthesis are integrated in the cell membrane. In a different but related study<sup>17</sup>, it was found that suspensions of *E. coli* cells, after freezing or incubation with EDTA or polymyxin B, participated in amino-acid catalysed ATP-pyrophosphate exchange. It was shown that the reaction took place at the cell surface of the intact cells. The reaction products were found extracellularly. The authors considered these results in terms of the possible localization of conventional amino-acid activating reactions at the cell membrane.

Stafford *et al.* found active polysomes bound to membranes in fertilized sea-urchin eggs<sup>18</sup>. The major fraction of incorporated radioactivity was into a heavy, easily sedimentable fraction. Ribonuclease partially released ribosomes from this material, whereas 0.3 per cent DOC totally released radioactive ribosomes. Hultin found that the major fraction of amino-acid incorporation in fertilized sea-urchin eggs was accounted for by structures which reached the bottom of a sucrose density gradient (5-22.5 per cent concentration) in 60 min at 53,000g (ref. 19).

There are several recent investigations carried out with liver preparations which underline the importance of membrane-bound ribosomes in protein synthesis. Henshaw *et al.* showed both *in vivo* and *in vitro* that membrane-bound ribosomes accounted for virtually all the incorporation of amino-acids<sup>20</sup>. Although the authors suggested that this situation may be contrasted with that existing in cells lacking an endoplasmic reticulum, the work by Handler and Tani<sup>2-4</sup> in *E. coli*, already mentioned here, suggests that, even in the latter case, membrane-bound ribosome may be functioning.

Campbell *et al.* examined the amino-acid incorporating ability of microsomes, RNP particles released from the microsomes by DOC, and free ribosomes in the presence and absence of poly-U, and as obtained from normal and regenerating liver<sup>21</sup>. They concluded that the major synthesizing activity of the liver cell was associated with membrane-attached ribosomes, that the membrane plays a part in the control of the activity of the attached particles and that free ribosomes are comparatively inactive, but may be stimulated by adding RNA such as poly-U. Similarly, Howell *et al.*, as a result of incorporation studies with liver both *in vivo* and *in vitro*, have concluded that membrane-bound ribosomes are responsible for the bulk of the protein synthesis<sup>22</sup>. Von Der Decken concluded similarly that microsomal membranes play an important part in the synthesis of serum albumin<sup>23</sup>. This conclusion stemmed from the observation that although microsomes appeared to be capable of synthesizing serum albumin, and RNP particles released from microsomes could incorporate amino-acids, the released particles could not make serum albumin.

Several groups have investigated protein synthesis in mitochondrial preparations. Roodyn used rat liver mitochondria for the *in vitro* incorporation of amino-acids<sup>24</sup>. Afterwards he step-wise fractionated the labelled mitochondria by titration with detergent. He found

that the bulk of radioactive protein was in a fraction rich in phospholipid and RNA. Further fractionation showed the radioactivity to be closely associated with the lipoprotein components which Roodyn suggested were derived from the mitochondrial membrane. From *in vivo* labelling studies with rats, Truman also concluded that the site of incorporation of amino-acids in liver mitochondria is associated with the mitochondrial membrane<sup>25</sup>. In a separate *in vitro* study with ox heart mitochondria, Truman showed that the most highly labelled proteins were soluble in 50 per cent ethanol, and were of low density and low polarity<sup>26</sup>.

The cytological validity of an intimate association of ribosomal and membrane components receives support from recent electron microscopic studies of mouse pancreas by Sjöstrand and Elvin<sup>27</sup>. These workers confirm and extend earlier observations by Sjöstrand and Baker<sup>28</sup> and Hanson and Hermodsson<sup>29</sup> concerning the use of osmium-fixation as opposed to controlled freeze-drying in preparation for electron microscopy. They present evidence that the ribosomal material forms an almost complete carpet covering the membrane elements. The subdivision into particles that is more commonly observed they attribute to artefacts of fixation. Recent electron microscope investigations with *B. cereus*<sup>30</sup>, *B. megaterium*<sup>31</sup>, and *E. coli*<sup>32</sup> clearly show ribosomes and ribosomal clusters attached to membranes.

Investigations on the existence and turnover of lipoprotein and lipopeptides from a wide variety of sources continue to appear. With the clearer establishment of active ribosomes at lipoprotein membrane surfaces during their participation in protein synthesis, the potential significance of these findings is considerably strengthened<sup>33-35</sup>.

During the past several years it has become quite clear that the reactions of electron transport are structurally integrated into the fabric of the membrane of the mitochondria or bacterial cytoplasmic membrane. In such a structure, energy released by oxidation is converted to ATP via high-energy intermediates. The ATP, being water-soluble, is then available throughout the cytoplasm for energy-requiring reactions. Because protein synthetic reactions may be similarly integrated by a membrane, the suggestion was offered<sup>36</sup> that high-energy intermediates produced in a membrane may be directly used for protein synthesis without the necessity of being converted first to ATP. Bronk added considerable support to this idea in a study of energy-dependent amino-acid incorporation in rat liver mitochondria<sup>37</sup>. He found that, at concentrations of oligomycin which blocked the terminal phosphorylation steps leading to ATP formation, the incorporation of <sup>14</sup>C-leucine was not inhibited. Thyroxine and tetraiodo-thyroacetic acid both blocked phosphorylation of ADP while causing a stimulation of amino-acid incorporation, presumably by diverting energy in the direction of the protein synthetic reactions. The same question is the subject of a careful study by A. M. Kroon, with mitochondria and microsomes isolated from rat liver<sup>41</sup>. Although some of the evidence points to the direct utilization of high-energy intermediates, Kroon gives reasons why it is not conclusive at the present time. Handler and Jarett have attacked the problem in a different way<sup>42,43</sup>. Yeasts were grown under strict anaerobiosis with energy supplied by fermentation of glucose. In confirmation of earlier reports<sup>44-46</sup>, it was found that both DNP and azide, in concentrations which were capable of inhibiting oxidative phosphorylation, could block protein synthesis. It was determined that fermentation was not affected and that ATP-levels in the inhibited cells were equal to or greater than those in the uninhibited controls. DNP and azide had no inhibitory effect on any of the reactions involved in *in vitro* amino-acid incorporation when ATP was present. This was also true for reactions that were stimulated by the addition of poly-U. Since these two

## BRITISH ASSOCIATION MEETING IN CAMBRIDGE

### SCIENCE AND SCIENTISTS

By SIR CYRIL HINSHELWOOD, O.M., F.R.S.

President of the British Association

THE annual gathering of this Association is traditionally the occasion when men of science and laymen come as it were into conference, when the scientists try to explain themselves and expound what they are doing, and the lay world listens with varying proportions of excitement, sympathy, criticism, scepticism or amusement. Attitudes have varied. The early comments of august sections of the Press on the proceedings seem to have been inspired by the spirit of Dean Swift at his fiercest. Bishop Wilberforce acted the buffoon though his intentions can scarcely have been playful, and the well-known abbreviation of our title, while indicating that element of popularity which most nicknames connote, summed up what a large part of Britain in its heart of hearts long felt about science and all connected with it.

To many, however, the story has been a very great one. I remember in my youth being thrilled to the core at presidential addresses by Oliver Lodge and by J. J. Thomson. We were at the heyday of the Wellsian enthusiasm for scientific progress. Utopia and revelation seemed just around the corner. Let the scoffers scoff: let the die-hard upholders of the classics denounce science if they wished, or suggest that it was not quite the thing, it was nevertheless a wonderful and moving adventure. It had long been the affair of a small minority of people. The originators of the Royal Society had been exceptional spirits, though we should never forget how much more exceptional must have been those unknown men of genius who in the course of the long ages of pre-history harnessed fire, drew forth metals from their ores, tamed animals and cultivated crops. One would give much to know their unrecorded saga.

But science, which was once a private affair, has now become a public concern. Several things have contributed to this. Science in its own right made at length progress in the battle for a place in education, though vestiges of the old prejudices long survived. More important, everyone has become increasingly aware of the power of applied science to affect our lives. Sad to say, two great wars played a major part in this enlightenment, and, perhaps in consequence, some people fear the destructive powers of science more than they appreciate its beneficent gifts. But most will recognize that our own choice decides what use we make of our control over Nature, and what any one of us thinks the balance will be depends chiefly on whether he expects good or evil to prevail in the world generally. In the last resort I believe the majority

of people expect, on the whole, good to flow from the use of knowledge.

Apart, however, from a desire for practical benefit, something of the romance of science has spread widely, and here, not only inexpensive literature, but also radio and television, themselves the children of applied science, have greatly contributed to what can very nearly be called a revolution.

There is, nevertheless, not much doubt that more general interest centres on applied science than on pure science. Governments are anxious for economic advantages from technology, so too is industry, and so, on the basis of what he is told, is the ordinary man. Everybody agrees that we now need many more scientists, and that we have an even greater need of technologists or applied scientists. Rather ambitious plans, which it is to be hoped are all quite sincere and genuine, are laid for unprecedented expansion, and certainly the desire for new things and for the means to improve the common lot is widely felt.

All in all, at the present time, it seems not inappropriate to say something about science and scientists in general.

There is a certain lack of clarity in many quarters about the relation of pure and applied science, and that is the first matter about which I would like to say something. Scientists themselves were at one time commonly believed to be mainly concerned with practical ends, and indeed there are still people who think that scientists care only about gadgets and gimmicks. This is by no means true, and as a matter of fact, to-day, scientists who were once regarded as 'rude mechanicals' are now quite commonly criticized for neglecting practical ends. They are now reproached for not doing quickly enough things which they were once laughed at for doing at all. But it is no use being amused or resentful at this odd example of time's revenge. We must try to see more clearly what the situation is and what might be done about it.

The relation of pure science to applied science is exceedingly subtle and complex. The urge to explore, understand and depict Nature is by no means the same thing as the desire to master and control it, nor are the relevant talents and abilities the same. Some men of science have had a keen desire to see their discoveries turned to practical account: others have been indifferent. Some have even affected to despise utility; but this was, I fancy, rather a gesture of defiance to their nineteenth-century detractors.

History shows a long record of discoveries made by one man and turned to account by others far removed in space and time. This state of affairs was well enough when all these things rested with amateurs. But the problem of application has now to be much more squarely faced, the more so in that the great majority of scientists to-day are people to whom society has explicitly provided opportunities in the expectation of tangible and useful results. What then is the right policy to follow?

What would be quite useless would be any kind of Draconian edict that all scientific work must henceforth be devoted to demonstrably practical ends. There could be no surer way of rendering the future completely barren, since nearly all great technological advances depend on discoveries so unexpected as to be unplannable. Nature in her own time reveals her secrets to the patient questioner, and the plain fact is that Nature is infinitely cleverer than man. Pure science, therefore, cannot be dismissed as a polite amusement and it would be a great tragedy if people with a real vocation for it were seriously diverted in the supposed interest of utility.

Nevertheless, it is deplorably true to-day that of the very large numbers now joining the ranks of science far too few seem to be evincing the technological interests which the future calls for. Reflexion on the native genius of our country suggests that the mechanically minded, the adventurously practical kinds of people should be by no means rare. Why then do we hear complaints about the lack of recruits for applied science? This is a very complex problem with no short and simple answer; but I think that two influences have been important. The traditional second-class status of science in the Establishment tended to deter all save the minority with a real vocation for it. The efforts of this dedicated minority not unnaturally won for British science no little prestige in the world, enough in fact to make this same field seem the most attractive to the rapidly increasing number of uncommitted entrants. Some young people are reproached for what is now alleged to be snobbery in their preference for pure science. On most of them this is a quite unjust judgment. Some are led there by real vocation, some by example, some because nobody has offered them an alternative, and some because large sections of opinion still draw no distinction between pure and applied science.

If some fault in the system of values is responsible, then the blame lies rather with the climate of society which has withheld its due esteem from practical skills, and until recently from science itself, the real nature of which it misunderstood. There is also another very significant facet of the situation. Great technological advances are made, not necessarily by those with profound insight into the secrets of Nature but by those with alert, enterprising, ingenious but quite unacademic minds, in some ways at least as much men of action as men of thought, who ask the question not so much 'Why does this happen?' as 'How could this be done?' or 'What use could be made of this?'. In the past our educational system would largely have diverted young people of this sort from any kind of science, pure or applied, and their talents would have flowered in other fields, where the rewards were greater. The damage is then done, since clearly nobody can apply scientific facts if he does not know any of them to apply.

Another trouble with our traditional methods of education, selection and promotion is the unjustified primacy which we have accorded to skill in purely verbal expres-

sion. It is quite wrong to suppose that all thought is through the use of words. Non-verbal images can be just as important. Some people think with their hands, and we need to give much greater credit to manual skill than we do (oddly enough with the exception of athletics).

It may indeed well be, as things are, that some appreciable diversion from the pure sciences to the applied sciences is called for. If it is really true that there is any impression abroad among young people that applied science is in itself a sort of second best to pure science in the scheme of things, then it ought to be dispelled. The adventure of controlling Nature is no less great than that of understanding its deep secrets, and the building of bridges as much artistic creation as the building of abstract systems of thought. We should be foolish indeed if we rejected the creations of Michelangelo because they are hewn in stone and accepted those of musicians or writers because they exist only in the mind.

But by no means all the recruits for technology need come from pure science. Many indeed could and should come from quarters which society has hitherto discouraged from developing any interest in science at all. It appears that lately there has been a turning away from pure science too. But can we blame young people with uncommitted minds for not choosing a course which means harder work and smaller prospects of esteem. They still feel, no doubt, that their ultimate success and influence will be limited by the old slogan of the administrator who proclaimed that the scientists must always be on tap and never on top. The formula which should be followed is simple enough, however difficult its application may prove to the complex situations of real life. Since men with the talent and the temperament for turning knowledge to practical use may turn up anywhere, in any social stratum, in any academic discipline and with any general intellectual background, we should see that far, far fewer of them any longer remain ignorant of science and perhaps even proud of their condition, and that those who respond should not find themselves relegated to a subaltern status.

Another important question of the day, and one not unrelated to what I have said, is that of the organization of research. In the grand perspective of world history the interplay of discovery and application has been largely an affair of chance. Now we wish to guide and plan the process, to rationalize and accelerate it.

A popular idea sees the planning and direction of research as a logical process proceeding by obvious stages from point to point to a predetermined goal after an expenditure of time and money calculable in advance by accountants. It is unfortunately nothing of the kind. Anybody can state a goal, whether the cure of the common cold or the control of the weather, and the proper organization may provide money for the effort. But inspiration comes only to rare individuals: it floats up intuitively from the subconscious. It is communicable from a leader to a team only if the members have confidence in him, both as a man and as a scientist. In some respects the situation in scientific research is rather like that in a football match. The players, the best available, must know the rules and will with advantage have concerted some general lines of strategy. The overall direction of play is predetermined. But after the start each new development grows out of what immediately precedes it, and depends on the inspiration of individuals as much as on the understood policy. Any captain who tried to plan too much in too great detail would lead the team only to

defeat. The captain himself must be at least a competent player in his own right.

There is little place in scientific research for philosopher kings, prescribing broad human objectives to teams of docile scientists kept 'on tap but not on top'. Nor, however, is it expedient to leave the romantics, the artists, the creators and the dreamers in ivory towers (whether in affluence or poverty). Nor again is it wise to try to transform them, by persuasion or otherwise, into something radically different from what they are. The world would probably have been poorer had Beethoven been forced to carve statues. Nor is it any advantage to transfer all confidence to the practically minded inventor, who would eventually be left without any new knowledge to apply. Again and again the key to a great discovery has been an unexpected observation, but generally speaking if it is to be quickly fruitful it must have been made in the context of a well-defined pattern of thought and effort. The famous Fleming mould would not have meant much to an administrator or even a nuclear physicist. But quite apart from these anecdotal accidents, and more important, is the fact that as the chart of the unknown becomes filled in, judgment of the most profitable course to follow itself changes. Mysterious inlets may prove dead ends or may open into vast seas. Research on the distribution of energy in the spectrum of a hot body might have proved a mere student exercise in physics; in fact, it revolutionized the whole structure of scientific thought.

If we wish to plan research we can only do so by assembling a community of people with varied and mutually complementary talents, operating with strategic flexibility, and in an atmosphere of curiosity in which the members know and understand what the others are talking about and respect their leaders. We shall forget at our cost that an honoured place in such a community must be found for the dedicated thinker. We must remember the words of Newton who, when once asked how he made his discoveries, said: "By always thinking unto them. I keep the subject constantly before me and wait till the first dawnings open little by little into the full light".\*

No committee structure, however logical and tidy, will replace the devotion of which Newton speaks.

Let no one think that a scientific community can be led either on one hand by people uninterested in human relations, or on the other hand by professional humanists without real personal understanding of what science involves.

A great deal of nonsense has at one time and another been talked around the allegation that scientists are interested in things rather than people. I have only to look at my own friends to know that this is utterly untrue; but if it had any truth the fault would rest with the educational system of selection which has indeed quite often attempted to segregate impressionable youth in accordance with this false philosophy, and I am afraid may still occasionally try to do so.

The prescription for future success in applied science is, after all, humane enough: a well-assorted community of human types, the analytical, the creative, the enterprising, the manually dexterous, all enjoying equal status, so that each part of the task may be taken up by some when others have made their contribution. True, all concerned must know the rudiments of the same language,

the general idiom of science. Is this an impracticable demand? Is it an aim lacking in humanity or social conscience?

We hear a good deal of talk about speeding up the advance of discovery and application. We all hope this can be done. But let nobody suppose it can be done by mere administrative elaboration or by the imposition of political doctrines. Let us imagine that somehow we can find the right balance between democratic equality on one hand and incentive and leadership on the other, and that by some miracle we achieve an administration capable of fostering effort while curbing extravagance and waste: the fact will still remain that scientific research of a creative kind is a very difficult business, and that its application is both adventurous and laborious, calling not only for courage and skill but also for that old-fashioned commodity known as faith. If the spirit is to spread more widely from the relatively few individuals of the past the whole climate of society must be favourable.

I have spoken so far of the application of science, because at certain seasons the most urgent task may be to gather the fruit from the tree. But woe betide those who kill the roots of the tree in this process: and this thought leads to deeper matters. I have the honour to be addressing the British Association for the Advancement of Science. Let there be no doubt about it, science is one of the great activities of the human mind and soul, and in the last resort let us remember that society was made for men and not men for society. As Dante's Ulysses says to his companions: "You were not born to live like the beasts, but to strive after virtue and knowledge". The question why we pursue knowledge is, I suppose, only part of that wider and nearly unanswerable one, "What is the object of life?". Even if they cannot give a satisfactory answer to the riddle, many men will undoubtedly continue the pursuit. Some may answer that we pursue knowledge to gain affluence and leisure. What affluence and leisure are to be used for is a personal question. To pursue knowledge will probably be the reply of the true scientist.

How then do scientists work? Does their work change their attitude to existence? Most of the conventional generalizations about them are quite crudely wrong, as becomes obvious if one reads the biographies of a few.

The old-fashioned view, the infection of which still tends to be inherited, saw them as materialistic, ignorant or contemptuous of beauty and ethics, respecters of the narrow truth they can comprehend, and uninterested in human relations to the point of ruthlessness. Sometimes they have been seen as supermen who could open quick and easy roads to affluence, though, it must be said, latterly sometimes also as supermen who can be mass-produced by administrative strokes of the pen.

To see what kinds of generalization are possible at all let us consider briefly the case-histories of a few outstanding scientists of the last generation. We will begin with three great physiologists, all Nobel Laureates, who worked in related fields: Pavlov, who created the science of conditioned reflexes; Ramón y Cajal, who was described by Sherrington as the supreme analyst of the cellular architecture of the nervous system; and Sherrington himself, who charted the functioning of the nervous system as a whole.

The work of the Russian, Pavlov, on reflex responses has been much quoted in anti-religious propaganda and to a superficial view it might well seem to assimilate living creatures more closely than before to automata. Pavlov

\* This saying was first made known to me by my friend Prof. R. N. da C. Andrade. If he had not been a great scholar he would not have known it, and if he had not been a fine physicist I do not suppose he would have realized its force.

himself is said to have spoken of religion as a social conditioned reflex. He was reputed to have been tenacious, hardworking, exacting and occasionally intolerant, averse to mathematics, chemistry and to too much theory, and to have preferred muscular to mental satisfaction. He was, however, not the product of a scientific environment: his father was a provincial clergyman.

The Spaniard, Ramón y Cajal, on the other hand, was the son of a surgeon of sorts, who taught his son anatomy, but the boy spent most of his time reading romances, was ill-treated at school, apparently for objecting to Latin, and presently expelled to become the leader of a rebellious gang. His passions were sketching, verse, fiction and philosophy. Wonder was aroused in him when he first saw the blood circulate in the web of a frog under the microscope: he found it what he described as "an astonishing spectacle, an unforgettable event in my life", and surely it was an artist who had no sleep the night after he had first seen a finely stained preparation of cerebral cortex in which, as he said, "all was sharp as a sketch with Chinese ink on transparent Japan-paper".

Family influences interested Sherrington in medicine and he passed by more or less conventional channels into research. He grew up among pictures of the Norwich school, wrote poetry and it has been said of him that the poet was never deep down. Though he, more than any other man, elucidated the nature of nervous reflexes, he was strongly opposed to any mechanistic view of the world. "Mind," he wrote, "knows itself and knows the world: chemistry and physics, explaining so much, cannot undertake to explain Mind itself."

The work of these three men, revealing the marvels and subtleties of nervous mechanisms, could no doubt be cited to support the views of behaviourists and materialists. Pavlov may have been one: the other two were not, and Sherrington never ceased to protest against attempts to explain away the phenomena of consciousness. The trio differed in background, temperament and tastes. What they had in common was the passion for knowledge, for the discovery of things previously unknown, and for the unravelling of mysteries—a characteristic which reflects a strong vein of romance. Another major fact, and one which is true of most scientists, is the essentially aesthetic nature of the appeal which their work made to them. Ramón's wonder at the spectacle of the circulating blood and Sherrington's poetry are indications of it and it appears indirectly in Pavlov's love of collecting, which ranged from butterflies to paintings. But romantic curiosity and the enjoyment of wonder and beauty do not make the man of science unless they are allied to a deep wish not only to know but also to organize knowledge into a coherent picture of the world. Science, whatever else it may be, is a form of creative art.

Let us now see how these themes appear in the lives of some great physicists of roughly the same generation. Max Planck at the turn of the century revolutionized thought by revealing an essential discontinuity in the working of Nature. But he came from the most respectable stratum of the German Establishment of his time. If we seek to pluck out the heart of his mystery we may listen to his own words: "the outer world," he says, "represents something independent of us and absolute with which we are confronted, and the search for the laws which govern this absolute has appeared to me as the most fascinating work of a lifetime." Rivalling the passionate concern with the scheme of Nature was the love of music which was a major element in his life, and which he shared

with Einstein and with a surprisingly high proportion of physicists.

Another man who sought with adventurous boldness to depict the system of Nature was Eddington, who had a basically mathematical approach in his interpretation of the world, and spent the latter part of his life in a titanic attempt to find the inner relations between the microcosm within the atom and the macrocosm of the stellar universe.

Very different in origin and in his exuberant, extrovert personality was Rutherford, the New Zealander. Like Newton and like Wren, Rutherford had as a boy a taste for mechanical construction—though he was also no mean scholar and he also believed in keeping mathematics in its place. One of his reported *obiter dicta* is to the effect that no physical theory is worth much if it cannot be explained to a barmaid (a class of lady who still existed in Rutherford's day). He, too, had the intense energy and the concentrated urge to discover, and he, too, created his own pictures of the world of Nature, but ones very different from the abstract patterns of Planck and Eddington and based on conceptions of atomic structure vivid and powerful enough to appeal to the most simple-minded.

Just as these men differ, so does the actual idiom of scientific representation, which varies from the most concrete to the most intangible. Rutherford liked the most down-to-earth imagery. Yet he was far from simple-minded himself, and his own symbolization moved chemistry and physics forward by a generation. Einstein, on the other hand, brought facts and ideas about the speed of bodies and of light and about gravity into formulations, which some philosophers declared contrary to common sense and which certainly are of an extremely abstract character. Oliver Lodge, who presided over this Association just half a century ago, had a taste for more shadowy prescriptions. He wrote, "my instinct seemed to be more abstract, rejoicing in hidden forces... ultimately becoming more absorbed in the ether as a non-sensuous reality—than in the material objects themselves". But the primitive models of Rutherford, the elusive ether of Lodge and the Lewis Carroll-like mathematics of Einstein were no idle playthings. They were the working tools with which radio was developed, the existence of nuclear energy predicted, and the method for its release discovered.

The creations of various men of science may be likened to pictures by artists of different schools, all conveying essential truth but in varied forms. The individual nature of its symbolism lays science open to the attack of those philosophers who like to question minutely the use of language in every statement. Men of science, although some of them play at this game themselves, tend on the whole to be impatient of purely semantic discussions and indeed most of them would probably feel that present-day linguistic philosophy has been not unjustly described as an affair of limited risks and small returns. In many ways creative science is just the converse of this. A philosopher once told me that the now notorious second law of thermodynamics was not so much false as meaningless. So be it. Force and energy themselves as concepts can be subjected to destructive analysis yet these elements are combined by scientists into patterns which not only give artistic satisfaction but also lead to world-transforming practical discoveries. Newton's treatment of force and mass can easily be represented as a circular argument and Einstein's spatio-temporal schemes dismissed as illogical. Yet these things are part of the

foundation of nuclear physics, and nuclear energy and the hydrogen bomb, whatever else they may be, can scarcely be written off as meaningless.

The creative scientist is in fact usually more concerned with the relations of things to one another than with precise verbal analysis of what these things are. He seeks a representation of the world which continually grows by an extension or transformation of what is there already. Thus what many scientists are really after is the adventure of discovery itself.

Rutherford used to talk about science as though he believed—and he did believe—that wonderful new revelations and illuminations were just about to occur. We are at a most exciting stage, he would say. There is ample ground for such a feeling at the present time. The last section of this address will therefore be devoted to a brief survey of some of the great fields of present activity, and I shall try to say something of the fundamental problems of science which are of the deepest significance in their own right. By a strange uncovenanted mercy it is indeed the study of these, if history has any lessons to impart, which in the long run will have the greatest effect on human life. But I hope that what I have already said will have shown that this observation implies no reserve about the urgent necessity of other work of shorter range.

The questions which still remain the most absorbing are the oldest of all: the nature of the cosmos, the nature of matter, the nature of life.

People have, I suppose, always wondered about existence. The most primitive thinking scarcely distinguished the inner world of consciousness from the external world of space and matter, and many strange phantasmagorias of magic and myth have been conceived. Chinese philosophers saw in the world a conflict of positive and negative principles, and Pythagoras thought that geometry and number ruled the order of Nature. These systems are much more abstract than the atomic theory which even as expounded by the Greeks and by Lucretius gave a vivid idea of the hidden happenings underlying visible phenomena, and as developed in modern times served as a basis for most of the great triumphs of chemistry. But still more recently a great wave of abstraction has again swept over science.

What Jeans called the "Mysterious Universe" has lost nothing of the mystery which surrounds its structure, its origin and its history, and which extends to the stuff of which it is made and to the forces which act between its parts. But, in all these respects, lively imagination is continually playing on a stream of new discovery.

What is already known about the structure of the universe is surprising enough: thousands of millions of stars forming galaxies; countless galaxies rushing apart from one another with velocities which appear to increase with the distance from some assumed centre. This last fact has suggested, as everyone knows, that at some cosmic zero hour a vast central agglomeration might have exploded, the parts which then received the greatest velocity having by now travelled farthest. I must remark in passing that to identify this zero with a moment of creation seems to me neither sound science nor sound theology but a sentimental pastiche of both. To speak, moreover, of a beginning of time itself marked by this spectacular event seems meaningless. If this singular moment actually occurred it must have represented some sort of nodal point in a process on a still vaster scale, and of this we know absolutely nothing. But the words of

Hamlet to Horatio still remain one of the wisest warnings ever uttered.

The whole idea of a unique origin of things has its rival in that of a continuous creation of matter fed into the known universe steadily in the form of hydrogen, so that what we observe now may have persisted for all time (whatever the phrase 'for all time' may mean).

Experimental discrimination between the two theories is hoped for from observations on the remoter parts of space, but so far a definite or at any rate an agreed decision has not been achieved. In any event what is meant by continuous creation of matter raises questions as difficult and at present as unanswerable as those connected with the grand inaugural explosion. Against this bizarrely romantic background research continues with radio and optical telescopes, soon no doubt to be mounted in extra-terrestrial observation posts. Meanwhile Nature whispers warnings against over-simplification by revealing in very remote places the possibility of agglomerations of matter quite different from anything hitherto known, including what have been called 'quasi-stellar radio sources'. According to previous ideas these are much too far away for their brightness and are fantastically more energetic than they should be in the emission of radiation. In astronomy it would seem to be one of Rutherford's most exciting moments.

The gravitational forces acting throughout the universe present one of the most epic of all problems. Nothing has diminished the grandeur of Newton's conception of a force governing all the movements of the cosmos which he revealed for the first time as an understandable system. In the thought of Einstein this force, though its manifestations were very nearly in accordance with Newton's law, was not a real force but something simulated by the inherent geometry of space and time. Einstein's equations, however, lacked the fine simplicity of Newton's, and his thought, for all its power, had no finality. There has been a burst of renewed interest in relativity, and the theory of gravitation. If the geometry of space and time is a function of the masses present, what is mass? Mach had once suggested that the mass of any body arose somehow from its interaction with all the rest of the universe. Hoyle and Narlikar think they have overcome certain difficulties about this idea, and by combining it with Einstein's kind of space-time geometry have constructed a more unified theory. According to the equation which they develop there can be no description of 'empty space'. Space itself depends on what it contains and an empty world is a non-existent world.

If gravitation is the major force, or apparent force acting across the stellar universe, it has little to say about the structure and properties of matter itself, which has its own special mysteries in plenty. The intuition of the ancients that matter is particulate has stood the test of time, but the twentieth century has shown that the particles are particles with a difference. They behave in ways which are not easily describable in everyday language, though to a mathematician they resemble waves. Nevertheless the quality of discreteness remains, and between the particles a whole hierarchy of forces act.

Ordinary terrestrial life is very much an affair of chemistry, the whole panorama of which, including the variegated array of the elements and their properties, can be interpreted, on the whole very satisfactorily, in terms of the simple set of particles, proton, neutron, electron. But ordinary terrestrial life is an affair of low energies. In the stars and nebulae, Nature provides temperatures of

fantastic sounding magnitudes, and the great accelerating machines of modern laboratories provide, at fantastic sounding cost, energies which transcend many millions of times those met in ordinary chemistry. In this strange world of energy affluence and violence a bewildering collection of new particles appear. Some are heavy, some light, some are stable, some transient. They appear and dissolve: one type generates others. As discovery followed discovery it seemed that chaos and complexity were the rule of the subatomic microcosm. But at length some degree of order is beginning to emerge, though it is order of a rather peculiar kind.

The particles differ in mass and in charge: they differ in life-time and in the intensity with which they appear to act on one another. Powerful forces exist which are neither electrical nor gravitational. The bizarre appearances and disappearances of these entities prove to be governed by rules according to which various measurable quantities must maintain fixed relations, the so-called conservation laws. A system of numerical labelling of the possible modes of this particulate existence proves feasible, and it leads to the definition of abstract quantities known as 'isotopic spin' and 'hypercharge'. Observed values of these can be plotted one against the other on charts, and it now appears that the known particles (or particulate states) yield diagrams with striking elements of geometrical symmetry. This discovery indicated clearly an underlying law, and in 1964 a gap, a missing point, in one of these diagrams led to the finding of a hitherto unknown particle with even odder properties than usual (the 'omega minus' particle). Within the past few months there have been reported indications not merely of a new particle but of a new group of particles. What it all means is far from clear, but if we are here glimpsing a fundamental law of Nature it is certainly one which would have appealed to Pythagoras, for geometry and number are indeed coming into their own. The theories about these matters are now being made still more powerful by the introduction of considerations based on relativity, so in nuclear physics too it is one of Rutherford's exciting moments\*.

The non-electrical forces between sub-atomic particles are profoundly puzzling. Some are immensely powerful; some, acting in the same sub-atomic microcosm, relatively feeble. There are mathematical theories about them, which while far from comprehensive are in some respects of great power, as was witnessed long ago by Yukawa's feat in predicting one of the meson-type particles before it was ever observed. Here again we move in a strange world of mathematical abstraction.

The world of chemistry, many orders of magnitude larger, in which the drama, not of the weird sub-atomic entities but of the more homely, entire atoms and molecules, is enacted is in most respects a more comfortable one of those who like relatively concrete images of reality. Much is now understood, though plenty, both for enlightenment and for profit, remains to be discovered about the nature of metals, minerals, dyes, drugs, natural products of all kinds and artificial polymers, in respect of their structure, their transformations and their properties.

One of the greatest concentrations of recent effort has been on the physics and chemistry of living matter. There is now an essential understanding of the complex molecular patterns which, repeating themselves in endless permuta-

tions, can store information in the sequence of their units and in this way constitute a genetic code. A particular kind of chemical fitting together of complementary molecular structures is seen to play a major part in the replication of these codes during the multiplication of cells and the handing on of life. All this is a triumph of structural chemistry and of X-ray analysis.

It would be fallacious, however, to suppose that the major code-bearing molecules, the nucleic acids, can as a matter of pure structural chemistry replicate themselves in isolation. They do so only in the integrated organization of a living cell. The manner of this organization and the way in which it determines the characteristics of life are gradually being pieced together.

From the organization of the cell and the specialized structure of its surface the next step is to ask how cells can group themselves to form tissues and organisms. How the morphology of organisms is established and maintained is also a matter of chemistry and physics which is gradually yielding to patient search and thought. Great advances have been made in understanding the working of the nervous system, and we have a rough idea how that most subtle and elaborate of all computers, the human brain, performs its functions. The conceptions of molecular codes and the chemical storage of information which have arisen from work on reproduction have stimulated fascinating speculations about the mechanism of memory and even about the ancient mystery of dreams.

But what remains utterly incomprehensible is how and why the brain becomes the vehicle of consciousness. Great heat has sometimes been generated by debates about whether scientists will ever, as it has been crudely expressed, be able to make life in a test-tube. The heat at least is wasted. It need change little in our conception of things if they did. Suppose that in the course of centuries the transcendent technical difficulties are overcome, and that the appropriate enzymes, synthetic nucleic acids and so on are assembled together cunningly enough and that a cell is constituted. Suppose even that two suitable cells are made and unite and, in an appropriately controlled environment, develop into a man. The inscrutable mystery of the relation between this piece of chemistry and physics and the conscious mind remains precisely the same as if the cells were formed by the biochemical processes of human bodies. Some philosophers have wanted to talk away the mind-matter problem as a mere verbal confusion. I suspect that at bottom they simply attach no importance to the scientific description of things and are therefore indifferent to any divorce between it and the language which describes the world of conscious experience. If so, they are of course entitled to remain indifferent; but men of science presumably do not.

At all the boundaries of science we come up against what are probably the inherent limitations of human understanding. At the edge of biology we meet the chasm between what science describes and what the mind experiences. In the physical sciences, too, we encounter insoluble contradictions if we try to contemplate the limits of space, or the beginning of time. Why, moreover, should numerical and geometrical laws govern the transformations of the transient entities of the sub-atomic world? If there is continuous creation in the cosmos, what can we really mean by this process? If reality is describable by a four-dimensional space-time continuum why does the time dimension present itself differently to our consciousness? If some universe of anti-matter, where our protons and electrons are replaced by their

\* In passing, I might remark that one sometimes wonders whether 'manifestations' would not be a more appropriate word than 'particles'.

electrical opposites, were to drift into ours a nearly inconceivable thing would happen. The two universes would annihilate one another and leave not a wrack behind. If Shakespeare has helped us to feel this event emotionally, the transformation of the whole world into energy is something which the intellect can grasp only in the form of a mathematical equation and, like that of so many other ultimate things, its essence seems to pass outside the framework of our comprehension.

There are, no doubt, some who on the basis of reflexions like this would depreciate the whole of science. But are they themselves sure that their own systems do not also contain ultimate incomprehensibilities and even inner

contradictions and that we are not all equal in the finitude of our vision?

If men of science are at all as I attempted to depict them earlier in this address, they are not perturbed by the limitation of their possible understanding. There seems at any rate to be no foreseeable terminus to their own adventure. If the canvas on which they represent the world is bounded it still has plenty of room on it to paint magnificent pictures which inspire the enquiring mind, delight those who have the sense of wonder, and, if the natural perversity of man does not frustrate the effort, show the way to benefit humanity for many centuries to come.

## SUMMARIES OF ADDRESSES OF PRESIDENTS OF SECTIONS\*

### PHYSICS OF RAINDROPS AND HAILSTONES

**I**N his presidential address to Section A (Physics and Mathematics), Prof. B. J. Mason outlines recent advances in the physics of rain and hail formation and demonstrates some of the experimental techniques used at the Imperial College of Science and Technology for investigating these processes.

*Growth of raindrops.* Raindrops are formed either by the melting of snowflakes and hailstones, or by cloud droplets of differing sizes and fall-speeds colliding and coalescing to form larger drops. In the latter case the growth rate of a drop depends on its collision cross-section for smaller drops and whether, following collision, the drops coalesce or bounce apart. Theoretically this problem is difficult and, though some progress has been made with the help of large computers, definitive answers are sought in the laboratory.

Experimental work has recently been greatly facilitated by the invention of a vibrating-needle device capable of producing droplets of very uniform and controllable size. Collection efficiencies have been measured for drops of radius 20–60  $\mu$  colliding with droplets of radius 1–12  $\mu$ , and accord well with theory. An important fact, predicted by theory and confirmed by experiment, is that drops of radius < 18  $\mu$  fail to collect droplets of any smaller size. These experiments, supported by high-speed photography of colliding droplets, show that collisions produced by differences in terminal velocity are almost always followed by coalescence, and separation is rare. However, similar droplets impacting at relative velocities of metres/sec rather than cm/sec oscillate violently after coalescence and break up again.

Collisions may occur between equal-size drops falling at near-terminal velocity if one enters the wake of the other. Photographs of such events show that collisions occur only if the drop radius exceeds 85  $\mu$  and the Reynolds number exceeds unity. When two drops collide, the barrier to coalescence is presented by the air film trapped between the drop surfaces, and this has to be expelled by the action of dynamical, gravitational, or electrical forces working against the viscous resistance of the air. The basic physics has been investigated by studying the impaction, bouncing and coalescence of small water drops at a plane

air-water interface. Whether the drops bounce or coalesce depends on their size, impact velocity and angle of incidence, and drops striking the surface normally behave quite differently from those which strike nearly tangentially. Deformation of the droplet surface on impact assists in the draining and rupture of the air film and raises the probability of coalescence. Drops carrying a net electric charge and drops polarized in an applied electric field coalesce with the water surface more readily than uncharged drops of the same size and impact velocity.

Summarizing, then, we now have fairly reliable data on collision efficiencies for water drops in air, with experiment and theory in reasonable accord, and evidence that gravitationally induced collisions are followed by coalescence. Applying these data to the growth of raindrops in model clouds with simplified patterns of the air motion, we find that raindrops may form by coalescence in summer cumulus clouds provided that they are sustained by upcurrents of at least 1 m/sec, attain depths of at least 1 km, and persist for at least 1 h. The extent to which these conditions may be relaxed by the action of electric fields and turbulence in the cloud is not yet certain, but it seems that these effects are unlikely to be very important.

*Structure and growth of hailstones.* Hailstorms occur most frequently in the continental interiors of middle latitudes where they cause extensive damage to crops, buildings and livestock, and present a serious hazard to aircraft. Hail damage in the United States is estimated at 100 million dollars per annum.

Hailstones vary widely in shape: spherical, ellipsoidal, conical, discoidal and irregular forms sometimes occur in one storm. The surfaces of the stones may be smoothly curved, scalloped, or irregular with protuberances and spikes. In size they range from currants to grapefruit. The largest stone ever reported, from Nebraska, was 5.4 in. in diameter and weighed 1.5 lb.

A hailstone may originate either on an ice crystal or a frozen raindrop and grow by the accretion and freezing of supercooled cloud droplets. The structure and mode of growth have been investigated by studying natural stones and by growing artificial stones in the laboratory. The internal structure is studied by viewing 0.5-mm slices under the microscope in both transmitted and polarized light. The crystalline structure, as revealed by the size, shape, spacing and orientation of the component crystals,

\* At Sir Peter Medawar's request, an abstract of his presidential address to Section D (Zoology) is not published in this issue of *Nature*. It is hoped, however, to publish the full address in a later issue.

is determined by many factors, such as the number concentration, size and impact velocity of the supercooled droplets, the temperatures of the air and hailstone surface, and the detailed mechanisms of freezing.

If the surface temperature of the ice pellet is well below  $0^{\circ}\text{C}$ , the impacting droplets freeze individually to produce a rimed structure of low density and composed of many small crystals. During rapid freezing at these low temperatures, numerous tiny air bubbles are released, remain trapped in the ice, and scatter light to give the ice an opaque, white appearance. On the other hand, if the transfer of heat between the pellet and the environment is just sufficient to allow all the deposited water to freeze and maintain the surface temperature at  $0^{\circ}\text{C}$ , freezing proceeds slowly, the droplets have time to spread over the surface before freezing and then produce a compact, glaze ice of high density, composed of rather large crystals with few air bubbles, which is transparent.

If the hailstone grows larger than about 1 cm in diameter, it is likely to collect supercooled water at such a rate that it cannot all freeze immediately because the latent heat of fusion cannot be conducted sufficiently rapidly to the air. Only a fraction of the water freezes to produce a skeletal framework of ice that retains the remainder of the unfrozen water, the whole mixture being at  $0^{\circ}\text{C}$ . The hailstone now builds up a coating of wet, spongy ice which is often transparent, but sometimes contains small air bubbles which give it a milky appearance. The airflow past such a large hailstone falling at, perhaps, 30 m/sec may deform the spongy ice and produce an ellipsoidal or discoidal shape. Large stones are often composed of several alternate layers of opaque and clear ice which reflect changes of crystal size and air-bubble content of the ice, these being induced by variations of temperature and water content inside the cloud.

But why are giant hailstones so rare, and how is their manufacture in the cloud controlled? Large stones of 5 cm diameter have terminal velocities of about 30 m/sec

and any theory of their production requires that the cloud shall be many kilometres deep and contain updraughts of comparable magnitude to keep the stones suspended for growth periods of about 20 min. But, because a strong, steady updraught will carry a nascent hailstone through the supercooled region of the cloud before it can attain a large size, it seems necessary to allow it to re-enter this zone and continue its growth on a second journey. It has been suggested that if the updraught were intermittent, the hailstone might repeatedly fall from a high level and then be carried up again, but there is no evidence that the strong updraughts are intermittent.

However, these difficulties largely disappear when we recognize that, because in middle latitudes the horizontal wind usually increases with height, the updraught is not usually upright but strongly tilted. Particles which achieve insufficient size on their first journey in the updraught may be thrown out of it as they reach the tops of their trajectories, fall down outside it, and re-enter the updraught at a lower level. If the updraught speed increases with increasing height, then a small proportion of the re-entering particles having just the right size may be lifted slowly by the updraught, growing at such a rate that the increase in their fall-speed closely matches the increasing speed of the updraught, and acquire a fall-speed equal to that of the updraught where it is strongest. Finally, they will fall down through the updraught again and reach the ground as very large hailstones.

In other words, the storm acts as a sorting machine, winnowing out most of the stones and selecting only a few for growth to the largest sizes.

Although our understanding of the hail problem has greatly increased in recent years, we still have a great deal to learn about the organization and development of these damaging storms, in which the strong interactions between the dynamics of the air motion and the microphysical processes of droplet-freezing and ice-particle growth are of peculiar complexity.

## THE CHANGING FACE OF ORGANIC CHEMISTRY

THE Changing Face of Organic Chemistry" is the subject of Prof. D. H. Hey's presidential address to Section B (Chemistry). Organic chemistry is to-day passing through a period of change greater in scope and more fundamental in character than ever before. This is largely, but not wholly, due to the rapid advances which have been made in the development of physical techniques. Side-by-side with these advances must be placed what has been described as a "veritable hurricane of new theoretical concepts". Foremost among the physical techniques must be mentioned the various branches of spectroscopy, mass spectrometry, and X-ray crystallography. The full exploitation of these developments has not only accelerated the process of structure determination but it has also to a large extent taken away from the organic chemist much of the interest and significance of the part which he has traditionally played in the analytical degradation and synthesis of a complex natural product.

If the total synthesis of a complex natural product has no longer an essential part to play in the elucidation of a molecular structure, there is nevertheless still wide scope for the study of reactions and transformations, which reveal much more than merely the relative positions of the atoms in a molecule. The changing pattern in organic synthesis is illustrated by a comparison between the synthesis of equilenin by Bachmann, Cole and Wilds in 1939 with the achievements of Cole, Johnson, Robins and Walker (1958), Velluz and his colleagues (1960), and Crispin and Whitehurst (1963), in the more difficult

synthesis of oestrone in which stereochemical control plays a dominant part.

Recent developments in X-ray crystallography have made an enormous impact on organic chemistry. The year 1955, when Dorothy Hodgkin announced her contribution to the elucidation of the structure of vitamin B<sub>12</sub>, marked the beginning of a new epoch in the relationship between the organic chemist and the crystallographer, the consequences of which have yet to be fully realized. More recent work on the antibiotic cephalosporin C is cited as an example of the organic chemist and the crystallographer working as complementary partners.

Another characteristic feature of contemporary organic chemistry is the wider recognition of the participation of relatively unstable intermediates, such as the carbenes, nitrenes, benzyne and free radicals, in many organic reactions. Reactions of organic-free radicals are now widely recognized and examples are cited which show their relevance to a broad range of topics. These include the production of phenol and acetone from cumene, the reaction between acetic acid and ethylene to give butyric acid, the exploitation of fluorocarbon chemistry, the manufacture of nylon-7, and the mode of action of the new herbicides diquat and paraquat.

Recent advances in the scope, control and ingenuity of synthetic processes are well illustrated by the preparation for the first time of such structures as those of Dewar and Ladenburg for benzene, first put forward almost a hundred years ago but long since rejected. Even more remarkable are the syntheses of the hydrocarbons cubane

and conglomerates and of the interlocking ring structures known as the catenanes.

The power now placed in the hands of the organic chemist is changing the pattern on which for so long he has worked, but in doing so new and exciting possibilities

are opened up. The new organic chemist has been aptly described as "one who is versed in all the disciplines of chemistry from chemical physics to chemical biology and who may be called an organic chemist solely because he happens to work on the chemistry of carbon compounds".

## ROLE OF THE FIELD GEOLOGIST

WE are reminded by Dr. J. V. Harrison in his presidential address to Section C (Geology) that during the time of the French Revolution and also the Napoleonic Wars geology was evolving rapidly as field-work became popular and furnished abundant facts. Search for valuable minerals to keep established trades in existence had been going on for many centuries and had made rocks and ores familiar objects in some societies with special interests. Later, bedded rocks came to be recognized as having 'ages'. In most exposures the lower bed was the older and the higher one the younger. It was not until a century later that it was realized that ages of rocks could be given in terms of years. Fossils were discovered in many formations and their classification undertaken. Their distribution was found to be compatible with an age concept.

Superposition of strata and their fossil sequences were, and still are, the most reliable criteria on which to establish relative age relations. By the beginning of the nineteenth century William Smith had acquired an exceptional knowledge of the rock series in parts of central England and had developed a method for recording his observations by colouring and annotating topographical maps to show the distribution and structure of the rocks. This led him, after years of careful field work, to produce and publish in 1815 a geological map of England. Government-sponsored geological maps of Scotland and Ireland soon followed as well as those of certain countries overseas, for example France. At about the same time, groups of strata in England and Wales were being studied, compared, sub-divided and mapped. The description and recognition of the fossils which many of them contained helped to establish the series of 'systems' familiar to all present-day geologists. Rocks of all ages, from the oldest Pre-Cambrian to the youngest Pleistocene, were included in an acceptable working plan, a world-wide classification.

Geologists were thus able to compare observations made in all parts of the world. Whatever the quest, the geologist's instructions were much the same: observe, record and interpret. Each expedition required a map. The course of geological mapping in Britain was determined

by the availability of topographical maps published by the Ordnance Survey from 1801 onwards. These provided splendid base maps for the geologist; but in most parts of the world such base maps were not available. Even nowadays much of the time spent in geological exploration has to be devoted to the production of a base map. Sometimes this is done by using very approximate methods, as in Central America and Borneo, and sometimes by modifying more accurate ones, such as in Persia and Peru, to fit with the requirements of the time-table, but nowadays vertical photographs taken from high-flying aeroplanes help to establish accurate base maps. Experience has shown that the value of a geological map depends largely on the clearness of the exposures. Only the maps made in countries where exposures are good are easy to interpret, and where they are not, help has to be sought from physical and chemical techniques—this has only been possible since the end of the 'twenties when many useful techniques were refined. Gravity maps, seismic data, electric logs and concentrations of selected elements may help in some aspect of a particular enquiry.

If such geophysical and geochemical help is forthcoming, why, it may be asked, should geologists be retained? The answer lies in the fact that each of these methods yields evidence about only one feature of the structure beneath. Their value depends largely on the interpretation of the immediate results; the geologist has been trained by seeing and examining many rock structures. Someone must have knowledge of the rocks as they are, that is, as they are exposed on the surface of the Earth. In each generation they must be studied, and each student must start with something of the heritage handed down; by this means the new geologist can set out with freshly tutored eyes expecting to see something which has previously been overlooked and which may be a key to future revelations. Through discussion and contact with his colleagues in the field, the geologist can tackle the problems of present geology with enthusiasm yet retain a good sense of proportion. The field geologist is as essential to-day as he was when field geology first became fashionable 150 years ago.

## THE CITY REGION

ONE hundred years ago, the British Association, then meeting in Birmingham, concerned itself with the problem of the growth of the industrial town, drawing illustrations from the social conditions which were accompanying the industrialization of the South Staffordshire coalfield. To-day the problems of urban growth are on a regional, rather than a local, scale and, despite the progress made in town and country planning and in 'environmental control', they present problems of at least equal difficulty and challenge. One of the most difficult of these is the problem of the 'city region', and it is pertinent that Prof. M. J. Wise should choose this as the subject of his presidential address to Section E (Geography).

While much work has been achieved, or is in progress, the scale of the research effort is not yet adequate. In

Britain greatest attention has been focused on the city region of London. A. G. Powell's paper to Section E in 1960, and other studies of this and other city regions, have demonstrated the principal features of the changing urban form. These include the growth in scale of the operations of the city and the increasing intensity of their influence over an area of regional scale. The outward movement of population from the inner areas, the result of both planned and independent removals, has assisted the creation of an outer fringe of rapid population growth. The dispersal of light industry and some types of servicing activity are associated with this movement. By contrast, increasing economic activity in the central areas of the city and in some other parts of the inner area, coupled with improvements in transport opportunities, is linked

with a further growth of long-distance journeys to work. Changes in the relationships between existing and new service centres are noted, and increasing specialization of area within the city region is seen to be an emerging trend. Individual localities within the region change their functions and their forms. Relationships between towns and countryside within the region become closer and provide new problems.

Similar, if not identical, trends are to be seen in many lands and insufficient attention has been directed in Britain to the possibilities of comparative city region study. The growth of city regions is a phenomenon of almost world-wide distribution. Despite understandable differences, there are striking resemblances in the city region problem in countries of diverse character, for example, in Japan, Hong Kong, the U.S.S.R., Australia, India, as well as in Western Europe and in the United States. Comparative studies may throw new light on the forces promoting growth of the city region; on the processes of change; on the results of actions taken to contain rates of growth and to modify the newly emerging urban forms; on the relations between transport changes and urban growth; and on the new relationships between the city region and the national economies and between the constituent parts of the city region itself.

All these topics merit more attention from geographers. The excellence of past achievements in, for example, central place problems, town-country relationships and urban morphology should encourage the extension of research work into the problems of identifying the forces and processes of change. The detailed characteristics of individual city regions need to be established and compared. While there are recent examples of encouraging work, some major contributions are handicapped by lack of resources. There is a strong need for more interdisciplinary work both among social scientists and between them and architects, planners and engineers. The case for the formation of a national institute for urban research is a strong one.

While the concept of the city region has gained widespread acceptance recently, it is not in itself new, perhaps at least half a century old. While many British geographers have contributed to its development, the work of R. E. Dickinson is particularly noted. Further refine-

ment of the concept is needed. However, town and country planners should not expect to find ready-made solutions to such problems as the practical boundaries of appropriate planning regions emerging from academic work. Too little attention has yet been directed to the measurement of changes in the region. The concept is not a static one, as is sometimes assumed. City regions are in the course of continuous change and adaptation. New tools for analysis are required.

A dynamic view of the city region is especially necessary when planning policies are being devised. For example, new appreciations appear to be needed of the roles of central business districts. The problem of devising clear but adaptable regional land-use plans is especially difficult. The fact of city region growth must be accepted and plans laid to maximise its advantages and lessen its disadvantages. There are encouraging signs of new work in land classification which may draw back interest to the problem of agriculture in the city region. Some changes in the countryside are inevitable: urgent studies are needed if they are not to be disastrous. The problem of changes in transport facilities in their effects on regional land-use patterns is especially evident and points again to the need for more effective links between economic planning and physical planning.

Linked trends in planning thought, related to the use of 'growth points', 'counter-magnets', or development 'poles', are of relevance to the problem of the city region. In what circumstances can positive planning for such 'points' be of value either within or outside the city region? Again, further progress is necessary with theoretical studies.

The new forms of city growth override existing local government arrangements. How far does the regional nature of city growth provide possibilities for the creation of new forms of government and administration?

The scale of the city region problem is immense. While it presents vital problems for immediate decision, the long-term implications demand the establishment of research effort on a much larger scale than can at present be attempted. To this end both universities and planning authorities should contribute. Countries in many parts of the world look to Britain for guidance in the theory and practice of urban growth. There is a special task for geographers.

## IS INFLATION INEVITABLE?

FOR the purpose of his presidential address to Section F (Economics), Prof. E. V. Morgan defines 'inflation' as, "a situation in which either the national money income is growing faster than the national real income or there is a growing backlog of unfilled orders".

In many sectors of modern industry, neither prices nor wages adjust themselves to changes in supply and demand promptly and in a manner which will clear the market. The study of inflation, therefore, requires a theory which will explain how prices and wages are actually fixed.

Economists have sought to explain the movement of wages in terms of the demand for labour, the cost of living, the rate of profit, productivity, the 'pushfulness' of Trade Unions and considerations of 'fairness' as between different industries and occupations. A review of work in this field suggests that: (1) The demand for labour is an important influence, though it is somewhat less important than it used to be, and it may now operate largely through employers' expectations of how far they can pass on higher costs in higher prices. (2) Recent changes in the cost of living are a very important influence on present wage negotiations. (3) The growth of productivity is less important than considerations of fairness, so that indus-

tries with widely differing rates of productivity growth often have much the same increase in wages. (4) There is little evidence of a close connexion between the growth of wages and that of profits in Britain, though this connexion appears to be much stronger in the United States. (5) The relative 'toughness' in bargaining of employers and Unions has some independent influence, though it is largely a reflexion of Unions' fear of unemployment and employers' expectation of being able to pass on increases in costs.

Studies of methods of price-fixing are inconclusive, but it is agreed that many prices are fixed at a level below that which would maximize short-run profits; that they are changed at fairly infrequent intervals; that they tend to reflect changes in cost; and that they are not very sensitive to changes in demand unless these are large.

Prof. Morgan examines the genesis of inflation when some prices are adjusted so as to clear the market, but some prices and most wages are fixed in the way described here. It is concluded that: (1) Neither rising import prices nor rising profit margins can create a self-sustaining inflationary tendency, but rising wages may do so, unless restrained, at the risk of creating unemployment, by

monetary or fiscal measures. (2) The changes in supply and demand that are part of a progressive economy may impart an upward bias to the price-level. (3) Differences in the rate of growth of productivity between industries may also impart an upward bias.

It will be impossible to escape these tendencies while there is excess demand for goods or for labour, and the prospect of price stability and of long-run growth would be improved by running the economy a little less near to the absolute limit of capacity than it has been in recent

years. Other necessary conditions for the avoidance of inflation are the breaking down of expectations that higher wages costs can be automatically passed on in higher prices; and the use of a greater part of the gains from increased productivity to reduce prices rather than to raise wages or profits. Discussions between Government, employers' organizations and Unions can help in establishing these conditions, though it is necessary to guard against dangers of inflexibility which may be implied in an incomes policy.

## MAN'S USE OF NATURAL RESOURCES

PROF. E. M. JOPE, in his presidential address to Section H (Anthropology), points out that some natural resources have, in human hands, held high potential in shaping (or hindering) cultural development. It is man's awareness of his just place in a finely balanced ecology at both subsistence and cultural levels which leads to civilized fulfilment.

Some stages seem to have been particularly crucial in rising humanism. There is the long upsurge of controlled food-production through Asia into Europe and in the New World; there is the rise of metallurgy, particularly of steel, and the steepening rise of power-technology in the West from the Middle Ages onwards; and there is the increasing command over materials which has led to the creative molecular architecture of specifically designed synthetic substances.

The evolution of effective food-production was a long-protracted process, first in western Asia from about 9000 to 5000 B.C., there and in south-east Europe adapted to a particular range of terrains. We should not too readily assume that this pattern of farming was implanted ready-formed into the very different conditions of temperate Europe, to yield the viable food-producing way of life found extending across European temperate forests from the west Balkans to the North Sea coastlands during the fifth millennium B.C.

Early domestication of plants is perhaps a little better understood than that of animals which, in the initial stages, must be seen largely through the archaeological contexts of faunal remains differing little, if at all, from the wild. Biological data can, however, be most revealing of lines of ancestry in domestic stocks, particularly in the ancestral relations to be traced in their multiple protein systems, or even in polysaccharides. Such molecular genetics is of great potential, especially if it could be extended to the insoluble proteins such as keratins or those of bone structure, a residuum of which survives intact in ancient bone; it might also be applied to soft tissues preserved by special conditions, as with the Altai horses. With these insoluble proteins, two-dimensional mapping of the constituent peptides ('finger-printing') is probably necessary.

The use of traction animals, and hence of wheeled transport, is another aspect of controlled animal breeding, and properly designed harnessing of their effort is vital. Here the Chinese, as in many other matters, initiated crucial advances long before they appeared in the West, as with the padded horse-collar, or effective harnessing

of wind-power in sailing ships controlled through the stern-post rudder. But it was only through the social urge of the medieval West that these germs were exploited to lead into modern power technology. That England, even in later Saxon times, was well to the forefront of these medieval advances is well shown by recent large-scale excavations, as of the tenth-century water-mill system at Old Windsor.

Two inventions, the fire-piston and the crank, again initiated early in the Far East, were not exploited in combination as a source of powered continuous rotary motion until the great Western developments of steam engines in the nineteenth century and the internal-combustion engines of the twentieth century. In these, especially the former, Britain again led the field. Demand on her excellent coal resources increased all this (the rising province of industrial archaeology), yielding a large chemical industry from its by-product outfall.

The archaeology and social anthropology of food and power resources are of the greatest importance in planning the viable use of the Earth, and the avoidance of man-made desolation, again as much at the level of cultural satisfaction as of subsistence.

Unlike the more dynamic resources, static resources are restricted and not continually regenerated from solar energy or as part of a natural biological cycle. But by expanding the use of varied materials into a profusion of man-made and man-designed substances, man has deployed the resources of Nature into an advantageous ecological pattern. Most important of all was the rise of alloy metallurgy, the interim stage of bronzes, then the carbon- and, from the nineteenth century, the alloy-steels. The refined use of materials and of the subtle nuances of their texture for artistic expression must not be overlooked. The ultimate elegance is seen in our full understanding of structure in relation to behaviour in even the most complex molecules of Nature, and the recent development of artificial substances designed with increasing precision for specific purposes (molecular architecture or molecular structural engineering) is one of man's greatest ecological achievements, for he has thereby created renewable cycles from the simplest of raw materials, the atoms themselves. The implications of extending this molecular architecture to full genetic control are serious and must not be ignored. It remains to be seen how these and the further extension into nuclear architecture can influence the nature of human society.

## THE ENERGETICS OF RUNNING

FORTY years ago the subject of Prof. A. V. Hill's presidential address to Section I (Physiology and Biochemistry) was "The Physiological Basis of Athletic Records", and Mr. B. B. Lloyd reverts to Hill's theme in his

presidential address this year, applying Hill's arguments and ideas to present-day records in the light of modern views on energy stores and supply rates and on the relation between the power output of a runner and his velocity.

As Hill pointed out, the energetic economics of running depend on two fundamental relations. First, the total energy,  $E$ , available to a runner in a time  $t$  is a store of energy,  $S$ , added to the product,  $Bt$ , of a rate of energy supply,  $B$ , and the time. Secondly, according to the most recent work of Margaria and his school, the energy,  $E$ , needed for running a given distance  $y$  is proportional to the distance, independently of the velocity; that is,  $By$ , where  $B$  is about 65 calories per metre. Thus the total energy used in a race lasting  $t$  sec will be  $By + At$ , where  $A$  represents the non-running metabolism. Thus  $By + At = S + Bt$ , so that  $y = S/B + t(B - A)/B$ ; that is, distance run is a linear function of time taken.

This is well borne out by plotting distance against time for the world running records, ranging from 50 yards to 600 miles, which give six distinct straight lines. The first covers the sprints up to 20 sec, but it is a straight line only in so far as the effects of acceleration and the increase in oxygen debt with time cancel each other out. The second line runs between the half-mile and the mile, the energy store  $S$  being Hill's oxygen debt, and the rate  $B$  being determined by the maximum oxygen usage of which the runner is capable, which itself depends largely on the cardiac output. If the energy store corresponding with the oxygen debt runs down exponentially, there must be a linear relation between time and the logarithm of the vertical distance on the time-distance plot between the points for the sprints and the extension of the second line from the mile through the 1,500 m, 1,000 m and half-mile. This is indeed found to be so, the half-life of the energy store being about 18 sec; this means that all the records

from the sprints to the mile can be regarded as governed by a single exponentially declining store, of about 11 Cal, and a single rate of oxygen consumption, of about 5 l./min, yielding some 25 Cal/min.

The third line runs from the mile to 10,000 m (28 min), showing a slightly larger store and a rate reduced by a few per cent. The fourth line runs from 10,000 m to the marathon (2 h 12 min), a range over which not oxygen usage but fuel supply appears to be limiting. The fifth line applies to distances greater than the marathon up to more than a hundred miles. Most of the fuel used must come from outside the muscles, and the slope of the line is about half that of the second line. Finally, the sixth line covers intermittent running, at an approximate rate of 100 miles a day. The energy expenditure is about 10,000 Cal a day, twice that of the most energetic lumberjack.

This analysis has also been applied to the records of the past fifty years. There seems to have been a steady enlargement in the rate at which oxygen can be used, though not in the oxygen debt, and on present trends the mile, for example, will be run in 3 min 40 sec by the turn of the century. Sprints will show proportionately less improvement, distances beyond 10,000 m proportionately more.

The scantier records of women runners fit the foregoing analysis well. Women have shown a bigger rate of improvement with time than men. They also seem to be able to use up their oxygen-debt store of energy faster, so that it is possible that one day the momentary maximum speed of the champion woman sprinter will exceed that of her male contemporary.

## THE HEYWORTH REPORT, PSYCHOLOGY AND THE SOCIAL SCIENCES

IN view of the recent publication of the *Report of the Committee on Social Studies* (H.M.S.O., Cmd. 2660), it is apt that Prof. George Westby in his presidential address to Section J (Psychology) has chosen to treat, as a contribution to the inter-section discussion which has been planned for the Cambridge Meeting, some of the problems of psychology and the social sciences affected by its argument and recommendations.

The Committee on Social Studies, under the chairmanship of Lord Heyworth, had terms of reference from the Ministry of Education and Science "to review research at present being done in Government Departments, Universities and other institutions and to advise whether changes are needed in the arrangements for supporting and co-ordinating this research". Prof. Westby begins by laying special emphasis on the important, but recently misrepresented, fact that even in those university departments which have traditionally had close links with biological departments, psychologists have always been aware that their science had potentially high contributions to make to society at large. Far from being tied to laboratory benches the 'founding fathers' of the subject in Britain undertook considerable obligations in the applied psychology of industry, education, health and other government services.

It is suggested that attention should be directed to a radical recommendation which seems to be implicit in the Heyworth Report. This speaks of psychology departments as having had their "main interests" in the biological aspects of the subject. The proposal seems to be that 'social psychology', which has by some American universities been developed mistakenly in recent years out of close relationship with the biological experimental aspects of psychology, should be considered either as a 'social science' separate, in some critical sense, from experimental psychology and biology, or possibly (the

Report is not clear) that psychology as a whole is 'really' a 'social science' and should be the special concern of the proposed Social Science Research Council. In any event, it would appear that a rapid expansion of social psychology is proposed, marching along with the expansion proposed for the other social sciences.

A number of arguments are adduced by Prof. Westby which suggest a pause for reconsidering such proposals. The present shortage of scientific man-power in this field is acute and the first requirement, therefore, is adequate finance, earmarked through the University Grants Committee, for expansion at first-degree level. The increased output and improved quality at this level which would occur as a consequence would then support the proposed, and necessary, expansion of postgraduate training courses and research studentships. An advance in applied research at the present stage which was too rapid would result in disappointment and disillusion for the many friends that the social sciences have gained in industry and government. Furthermore, outstanding methodological and theoretical problems remain half-solved at the most; there is always a danger of distraction from these by the need (too often pressing in the applied fields) "to show something practical for the money". There are signs, too, that the present atmosphere of 'social science euphoria' is endangering university teaching standards; in psychology and sociology there must be no premature dogmatism. A rush of what can only be called 'social science fiction' in the guise of sociology tempts even practical and informed administrators into premature policy judgments on the assumption that there is firm 'scientific evidence'.

In these circumstances it seems unwise to uproot psychology or its off-shoot, social psychology, from the seed-bed of the natural sciences, either theoretically by denying any common methodology, or practically by making exclusive allies with the sciences of economics,

politics and sociology. This is not to suggest that there can be a 'pure' psychology. Psychologists realize, like sociologists, that 'man is a social animal', but the biological aspects of social problems become increasingly important with advance in the biological sciences.

For these reasons the organization of psychology within the degree-structures of some of the universities of traditional pattern still offers the best path of progress. Where psychology has membership of the three faculties of arts, science and social sciences, and has appropriate joint honours options in each, all the essential links of the

discipline, in conformity with the principle of the 'unity of knowledge', will be safeguarded.

It is suggested finally that the implementation of the 1946 Clapham Report, though perhaps more cautious and sceptical than would meet the changed situation of to-day, put the stress of any expansion in the right place—in the proper staffing of disciplines which are faced with especially time-consuming problems of applied research, in a period of explosive interest in the social sciences among sixth formers and a Robbins expansion which will probably, in these subjects, have been underestimated.

## PHYSICAL APPROACHES TO SOME BOTANICAL PROBLEMS

IN his presidential address to Section K (Botany), Prof. R. D. Preston considers the fine structure of plant cell walls as an example of the powers of physical approaches to some botanical problems. In common with all other metabolic products, the polysaccharides of plant cell walls are the consequence of a chain of enzyme-controlled reactions specified by the appropriate DNA, and he takes the opportunity both of examining the bearing of wall structure on cell growth and shape and of tracing back some steps in wall biosynthesis as they appear to be demanded by wall structure, as part of the chain of events leading from DNA to the expression of plant form.

The walls of almost all plant cells are based on a common plan involving, namely, an array of long thin rods (microfibrils) some 100 Å–300 Å in diameter and of indefinite length, embedded in a matrix. The rods are in part crystalline; so far as is known, they consist in all higher plants of cellulose, a  $\beta$ -1,4-linked glucan, though in some lower plants, all seaweeds, they contain instead a  $\beta$ -1,3-linked xylan with distinctly different physical structure and properties which are discussed. Whether glucan or xylan, the rods are strong in longitudinal tension; laterally they are bonded together through other polysaccharides in the matrix, giving a structure which is less resistant to tensions applied at right angles to microfibril direction. The (in this sense) anomalous condition of some other seaweeds, in which the crystalline component is  $\beta$ -1,4-linked mannan not organized into visible microfibrils, is not necessarily a departure from the common plan.

The mechanical properties of an array of parallel microfibrils are, therefore, anisotropic; in particular, such an array, when subjected to stress, creeps much faster when the direction of stress lies at right angles to the microfibril direction than it does when stressed parallel to this.

Since plant cells grow, at least in large part, through a yielding of the wall due to stresses invoked by turgor pressure, it follows that the rate of cell growth, and the direction of yielding of the wall and, therefore, the ultimate shape of the cell—and indirectly of the plant—should be a function of wall structure. Examples are given to show that, in those instances examined, these expectations are fulfilled. There is no doubt but that control of cell growth and cell shape is achieved in large part through wall structure. The control mechanism is, therefore, in principle on call from the first moment of deposition of the wall.

The details of wall architecture vary widely over the plant kingdom, but it is striking how many plants possess lamellated walls in which the constituent microfibrils of each lamella lie rather beautifully parallel to each other and in how many of these a single cell wall shows two or three different microfibril directions and no other. Detailed physical examination of these walls allows the main features of the microfibril-synthesizing and -orienting mechanism to be defined in principle. Each microfibril must be produced by end-synthesis through an enzyme complex which may be envisaged as particles larger in diameter than the microfibrils and attached to at least one end of each. These particles must be ordered at the surface of the cytoplasm, probably in cubic close packing. Such arrays of particles have been seen in the electron micrographs of formalin-fixed material, but since then, and much more convincingly, in freeze-splintered material in Frey-Wyssling's School at Zurich. It remains to be seen whether these can be identified with the particles shown by Hassid to build the glucose moiety of guanidine diphosphate glucose into cellulose, and to assess the significance of the microtubules now known in many cells to lie near to the wall-synthesizing cell surface.

## THE CHANGING AIMS OF FORESTRY

MR. C. W. SCOTT has chosen as the subject of his chairman's address to Sub-Section K\* (Forestry) "The Changing Aims of Forestry". The aims of forestry are to supply what is wanted from the forests, and as the demands change, so also must the aims. The trend of present demand is for woods of different type and size from those required in other centuries—or even recent decades. Growing wood is the primary function of forestry, though forests have other important functions.

Great changes are in hand to meet the swift rise of human populations and standards of living, and the rising demands for wood on a great scale in the form of plywood, man-made boards, and pulp and paper. Other causes of

change in forestry are new machines and the cost and limited supplies of labour. Work and life in or near forests are usually less attractive to labour than on farms or in towns.

*The demand for wood in Europe.* In 1964 the United Nations published a valuable study in detail of the demand for wood in Europe, excluding the U.S.S.R., during the period 1900–2000, and specially the period 1950–75. During 1900–50 the growth of demand was modest; but during 1950–75 this demand is likely to double, with larger imports. By the year 2000 the gap between Europe's annual growth of wood and her annual use may be 100–160 million m<sup>3</sup>, or some 3,500–5,000

million ft.<sup>3</sup>. A.D. 2000 is only thirty-five years ahead, or about half the time that it takes to grow a fair Scots pine saw-log in the north of Britain. The magnitude of the foregoing estimate of future demand may be compared with the planned initial needs of the new pulp and paper mill at Fort William, Scotland, which are for some 15 million ft.<sup>3</sup> (true) per year. It will strain not only the present Scottish forests (predominantly young Sitka spruce in that area) but also the present roads to supply 10 million ft.<sup>3</sup>. The balance must be imported.

Sawn wood is losing ground to man-made panels of wood pulp and other materials, but the demand for sawn wood is still immense and likely to remain so if it is cheap enough. But the demand for wood-pulp is growing much faster. By 1975 half the total demand for wood in Europe is likely to be for pulp and panels, with obvious effects on silviculture.

*The growing of wood in Europe.* There is a change of emphasis from slowly growing trees, like oak, to faster trees, such as poplar, eucalypts and conifers, and especially the faster conifers such as certain pines and Sitka spruce. Poplar gives four times the annual volume of wood per acre than does oak; and in France a quarter of the total annual cut of broad-leaved trees is now poplar. Prime oak has special value, but the day of oak coppice for fuel is over, or at least passing. The climatic, soil and water demands of various trees govern what can be grown well on any given site, but where there is a choice to-day it is rightly for the faster and cheaper production of what the markets want.

How much wood Europe is to grow for itself and how much to import is a problem in land use and economics. So also is the matter of helping poorer countries by buying their surplus wood, if any, if only to help them buy European machinery with which to help themselves.

In northern Europe the annual growth of wood averages about 1–3 m<sup>3</sup> per hectare, with a tree-life or rotation of about 100 years. In the warmer south and south-west of Europe the faster species grow at 15–20 m<sup>3</sup> per hectare per year, on suitable sites, with a rotation as low as twenty-five years, or lower for coppice. Slowly grown coniferous wood has special physical values, and both slow and fast wood are needed; but slowly grown trees alone cannot meet the future demand in Europe, and still

less so in Asia and Africa. The rising cost of forest labour and the need for mechanization with simplified and cheaper production favour even aged plantations of one species in each block, and blocks of considerable size. Monoculture is no more to be deplored in production forestry than in agriculture, with proper soil maintenance and steps against pests.

*The defects of some natural forests.* The late T. R. Peace warned the British Association in 1960 how wrong it is to worship blindly the "natural forest" as a desirable aim. The virgin rain forests of the Amazon are the greatest in the world but they export very little timber because the species are in general too hard and heavy, and often contain silica and extractives. The rain forests of South-east Asia and West Africa are at present much more valuable to man because they provide exports of moderate- or light-weight timbers. One reason for this difference may be that the Amazon has been less disturbed; and human disturbance tends to bring in the lighter wooded trees, provided of course that the disturbance is not too severe.

The wild rubber (*Hevea*) trade of the Amazon flourished until about 1914 but was soon eclipsed by plantations of the same tree in South-east Asia. Even now the latter survive against synthetics only by cheap production, helped by abundant labour and tree breeding which has raised the annual output per tree five-fold.

*The future.* How much land and what land should be used for farming, forestry, recreation and nature conservation is a problem in land-use in Britain as elsewhere. Western Europe and America north of the Rio Grande are not typical of the world as a whole, in which many millions lack adequate food, fuel, housing and education. For the last of these four, paper seems likely to be wanted on an immense scale. By the end of 1964 about 11 million acres of fast-growing tree plantations had been made in the poorer countries alone, with eucalypts, true teak (*Tectona*) and fast pines such as *P. radiata* and *patula* prominent. Even if pulp and paper are eventually made on a grand scale from materials other than wood, it is likely that cheap wood will long be wanted by the world as a whole: but, as the late W. E. Hiley used to emphasize, the cost of production is vital, and the consumer has the last word.

## TECHNOLOGY IN A LIBERAL EDUCATION

IT is commonly thought that the antithesis between 'liberal' and 'technical' education goes back to the ancient Greeks. This is at most only partially true, as J. C. Dancy points out in his presidential address to Section L (Education). The Greeks of the Golden Age respected the crafts along with the arts. It was Plato who invented the caste-system which set ideas above matter, theory above experiment, pure above applied learning, and which linked epistemological with social distinctions.

Plato's influence has distorted the British theory and practice of education. That influence has been exercised in part directly, but in part also through the great thinkers of the early nineteenth century, especially Coleridge. Plato was one of the ancestors of the Romantic Revival, whose hatred of the Industrial Revolution and emphasis on literary values have for years dominated our educational thinking. Add these ideas to the traditional English social caste-structure, and you are in for trouble.

In the past hundred years 'pure' science has broken through the barrier of socio-academic respectability, but technology has still to do so. Yet some aspects of technology deserve a place as an integral part of a truly liberal education. No school would call its curriculum liberal

unless it offered its pupils the creative experience of art and music. So all pupils should be given the opportunity of making things which work—the opportunity provided in such places as Mr. Gerd Sommerhoff's Technical Activities Centre at Sevenoaks School, Kent. Such work is creative in three separable senses: it requires and develops the creative activity of mind, hand and eye; the activities of the scientist, the artist and the craftsman.

Intellectually, technical project work can restore to science in schools the challenge, the excitement, the uncertainty, the open-endedness which traditional school syllabuses and approaches (not excluding practical work) have gone so near to killing. Aesthetically, such work contains an element of design which is distinct on one hand from styling and on the other from efficiency, and is analogous to elegance in mathematics. Nor, thirdly, can we afford to scorn the skills of the craftsman: an activity in which hand and brain work together is a supremely human activity.

Technology is indeed in many respects a bridge between science and the humanities. It may even be that the psychological make-up of the engineer is nearer to that of the artist than to that of the scientist, and that the country's shortfall of engineers should be made up from

the ranks not of our science sixth forms, but of our arts sixth forms.

Over and above such theoretical considerations, the art of making things which work is one which gives great

satisfaction to the individual—a matter the importance of which increases *pari passu* with the increase of leisure—and which obviously stands to benefit society, both in the advanced and in the underdeveloped nations.

## ASPECTS OF SOIL, PLANT AND ANIMAL RELATIONSHIPS

**D**URING the past fifty years much has been learned about soil conditions in relation to both plant growth and animal health. In particular, it has been recognized that, in addition to the accepted major nutrients, trace amounts of a number of elements are essential to both plants and animals. It is this aspect of soil-plant-animal relationships which forms the main theme of Dr. A. B. Stewart's presidential address to Section M (Agriculture).

Because of variations in environmental and soil conditions as well as in crop and animal requirements, soil-plant-animal relationships are necessarily of considerable complexity. Unlike the plant, the animal may derive much of its food from sources unrelated to its immediate environment. Direct relationships between soil conditions and animal health are in consequence more difficult to establish than are corresponding relationships between soil conditions and plant growth. On the other hand, intensification of agriculture and restriction of livestock to narrower ranges of soils has undoubtedly done much to direct attention to specific mineral deficiencies. Refinements in analytical procedures, the availability for experimental purposes of radioisotopes of most of the biologically important elements, and developments in the field of enzymology have all contributed substantially to the striking advances which have been made in knowledge of the mineral, including trace-element, requirements of plants and animals. With continuing advances in these and allied fields of research, it is probable that certain of the elements at present regarded as non-essential may be found to play vital parts in plant and animal nutrition.

Following discussion of soil conditions in relation to plant growth, reference is made to the various macro- and micro-nutrient elements now known to be essential for either plant growth or animal health or both. These include carbon, hydrogen, oxygen, nitrogen, phosphorus,

potassium, calcium, magnesium, sulphur, sodium, iron, manganese, copper, zinc, boron, molybdenum, cobalt, selenium, chlorine, iodine, and possibly fluorine, bromine, barium and strontium. Others such as aluminium and silicon are beneficial to some plants under some conditions, but the possible significance in agriculture of many elements which are taken up adventitiously by plants is still uncertain.

The principal factors determining the trace-element status of soils in Britain are soil parent material, drainage conditions and degree of acidity or alkalinity. The trace-element composition of plants depends, however, not only on soil conditions but also on such other factors as genus, species or strain of plant, environmental conditions during growth and, because of seasonal variations, the stage of maturity at which the plant is gathered or consumed. In many instances the incorporation into fertilizers of an appropriate quantity of a particular element may be a simple means of remedying trace-element deficiency in soil. It is of the greatest importance, however, to remember that with trace elements the range between deficiency and excess is a narrow one, and that unnecessary application of trace elements to a soil increases the risks of possible toxicity associated with the build-up of trace elements in available form. Toxicity conditions associated with the natural occurrence in soils of excessive amounts of certain elements such as nickel, leading to crop failure, and molybdenum and selenium, affecting adversely the health of livestock, are not uncommon. In Britain, geological complexity and the transport of soil parent materials during periods of glaciation have led not only to regional but also field-to-field variations in soil contents of biologically important trace elements. Under such conditions the indiscriminate application of trace-element supplement as a general insurance measure against possible deficiency is inadvisable.

## THE SOCIOLOGY OF SECULAR RELIGIONS

**T**HE purpose of Prof. D. G. MacRae's presidential address to Section N (Sociology) is to attempt to correct a widely spread set of beliefs about modern industrial societies—beliefs which are held both by the lay public and professional sociologists. Its second intention, which is a consequence of the first, is to correct certain largely unconscious assumptions of theoretical sociology.

It is widely accepted to-day that we are living in a period of intense secularization and that modern societies, particularly industrial societies, are the furthest advanced along this road. Churches and church attendance are believed to be in decline; material and scientific values are believed to be replacing non-natural and religious values, and patterns of behaviour based either on scientific procedures or economic calculation are believed to be becoming dominant in our societies. In a word, our societies are supposed to exemplify in an extreme form the process characterized by the German sociologist Max Weber as "increasing rationalization".

It is, of course, not the intention of this address to deny the importance of scientific procedures or their increasing role in our societies. No more is it the intention to deny that organized religion in Britain has probably less grip

on the general public and less affects our social structure than was true in the past or than is true in almost any other non-Communist society (equally, as Prof. MacRae states, it is not intended that the very high rate of religious observation in the United States should be explained away). Rather, what is claimed is that we are in a period in which there is a marked rise in secular religions.

By secular religion is meant: (1) The spread and elaboration of belief-systems based on non-natural authority, usually accompanied by specific ritual systems, and usually offering individual consolations based either on ordinary technical factors or on day-to-day social relationships. (2) In the strict sense these non-secular religions usually involve the idolatry of abstract idols: nationalism and communism will both be examined from this point of view. Not all secular religions, however, carry such heavy political weight, and various forms of scientism (including sociologism) are examined—by scientism is meant the idolatry of the appearance and the mimicry of the forms of natural science and specific technologies.

In addition, it is argued that the contemporary world is pervaded by various forms of mythical thought. This

latter term is understood in the sense used by Cassirer in his *Philosophy of Symbolic Forms* and used also by such prehistorians as Frankfort. The connexion of the mass media advertising and new culture heroes and heroines with contemporary myth is outlined.

Consideration of these social realities of our time must involve a criticism of one of the fundamental aspects of sociological theory: this is the unstated idea that some sort of equilibrium system or balance sheet formulation can be used in sociological study of religion and ideology.

Rather is it suggested that the logical incompatibility of ideological elements is no barrier to their simultaneous growth and development in social structures, although in certain specific circumstances such incompatibilities may emerge and be of real importance in precipitating radical social change. Finally, an attempt is made to relate the account of contemporary secular religion and the criticism of sociological theory that this account entails to the general sociology of religion current among contemporary sociologists.

## SCIENTIFIC UNDERSTANDING AND THE CHIEF END OF MAN

SINCE the collision between T. H. Huxley and Bishop Wilberforce at the British Association meeting in Oxford in 1860, further radical advances in scientific understanding have taken place. The enormous industrial productivity of a modern State is based on Faraday's studies of electromagnetism, the work of Joseph Black on latent heat underlying the perfection of the steam engine, chemical researches into large molecules leading to the present plastics industry and, more recently, on a combination of investigations of solid-state physics culminating in the development of transistors combined with Babbage's conception of a general-purpose digital computer. Dr. Magnus Pyke, in his presidential address to Section X (General), considers that all this and more is bringing about a state of affairs when earning a living can no longer be considered a major goal of human endeavour.

In the past hundred years, advances in chemistry and biology have changed men's ideas of the nature of famine and pestilence. The yields of arable crops have been consistently increased by the use of chemical fertilizers and, above all, by the breeding of improved strains of both plants and animals. Statistical evidence has been presented by Mayer<sup>1</sup> suggesting that the proportional increase thus achieved in world food supplies during the past two decades has been greater than the parallel increase in population and that this is part of a general trend that has been proceeding since the 1850s. The effect of scientific advance on medicine has been even more profound. Understanding of the nature of infectious diseases originated with Pasteur; aseptic surgery, anaes-

thetics and immunology are further examples of new knowledge; and chemotherapeutic agents and antibiotics were only developed by scientists of the present generation.

Great though the effect of scientific understanding has been on man's material condition, its influence on his thought and belief has been more profound still. Earthquakes and epidemics can no longer be feared irrationally as capricious retribution for public sins, nor need individual illnesses any longer be attributed to the evil eye. The universe has become a rational and, in many respects, a controllable place. The nature of the intellectual process which constitutes science which has brought this about can be seen to be an amalgam of observation, reason and imagination constantly refined by repeated reference back to Nature. Science can thus in many respects be compared with poetry as a way of finding truth. The present intellectual schism is between those who base their behaviour on dogma and those who put their faith in the belief that the exercise of reason and imagination in search of truth is the basic human goal.

MacKay<sup>2</sup> has already pointed out that it was concern for truth which begot science, not science which begot concern for the truth. It is argued that to continue to pursue the truth, which is, in its essentials, the pursuit of a moral goal, by means which have already successfully brought material wealth, food, healing and understanding of Nature and of man himself, is a worthy end for human endeavour.

## PRESIDENT FOR 1966 OF THE BRITISH ASSOCIATION

SIR JOSEPH HUTCHINSON, C.M.G., F.R.S.

SIR JOSEPH HUTCHINSON, Draper's professor in the University of Cambridge, has been elected president for 1966 of the British Association for the Advancement of Science. Sir Joseph will deliver his presidential address at the next annual meeting in Nottingham.

Sir Joseph succeeded Sir Frank Engledow in the chair at Cambridge in 1957, and to repeat that which appeared in *Nature* on that occasion should indicate sufficiently that the British Association has made an excellent choice in the successor to Sir Cyril Hinshelwood as president.

Sir Joseph was born in 1902 and was educated at Ackworth and Bootham Schools, and at St. John's College, Cambridge. After graduation, he took a postgraduate course at the Imperial College of Tropical Agriculture, Trinidad, and then joined the Empire Cotton Growing Corporation's Cotton Research Station as assistant geneticist in 1926, the year in which the Station was established. He soon proved himself a worker of notable quality, and began a long series of researches on the genetics and taxonomy of the cotton plant which ultimately established him as one of the world's leading

authorities. After seven years in Trinidad he gained further valuable experience in India, where he was from 1933 until 1937 geneticist and botanist at the Indore Institute of Plant Industry. Returning to Trinidad as chief geneticist at the Cotton Research Station, he continued, with the aid of his colleagues, Dr. R. A. Silow and Dr. (now Prof.) S. G. Stephens, the elaborate series of genetical and evolutionary studies on the genus *Gossypium* which culminated in a joint work entitled *The Evolution of Gossypium and the Differentiation of the Cultivated Cottons*. This book was highly praised and takes its place among the classics of biology as perhaps one of the most comprehensive studies of the evolutionary history of a single genus ever carried out.

With the shutting down of the Trinidad Station in 1949, Sir Joseph went to Uganda as the first director of the Empire Cotton Growing Corporation's Cotton Research Station at Namulonge. Elected to the Royal Society in 1951, he was knighted in 1956. Since 1953 he has served as chairman of the Council of Makerere College, the University College of East Africa.

(Continued from page 1054)

different poisons are known to be related by their effects on the reactions involved in converting high-energy intermediates to ATP, the findings are interpreted in terms of the necessity for ATP to communicate with the high-energy intermediates of the terminal stages of oxidative phosphorylation in order to energize the *in vivo* synthesis of proteins.

Thus it is seen, from a wide variety of different approaches, that the evidence pointing to the importance of structural organization for protein synthesis is accumulating. Biochemistry has made remarkable advances by dissecting the cell into various independent metabolic steps. The cell is a structure which is composed of structures. Protein synthesis represents the combined activity of many integrated reactions which deal with precursors, flow of information, energy supply, interlinked enzyme reactions and controls. It is not surprising that the search should now be turned back into the cell to find places for the various parts that have been studied in isolated systems.

## LOCALIZATION OF GAMMA-GLOBULIN WITHIN INCLUSION BODIES OF L. E. (LUPUS ERYTHEMATOSUS) CELLS

By DR. T. TAKAHASHI, PROF. C. L. LEE, DR. C. BIAVA and PROF. I. DAVIDSOHN

Departments of Pathology, Chicago Medical School and Mount Sinai Hospital, Chicago, Illinois

**I**NCLUSION bodies of L. E. cells are derived from nuclei of leukocytes as a result of changes induced by the L. E. factor present in the serum of patients with systemic lupus erythematosus. The mechanism of action of this factor and the nature of the changes responsible for the transformation of nuclei into homogeneous inclusion bodies are not yet fully understood. Histochemical investigations have shown that the altered staining properties of the DNA in inclusion bodies with basic dyes is due to the presence of increased amounts of proteins foreign to normal nuclei<sup>1</sup>. More specifically, investigations with immunofluorescence techniques have demonstrated that inclusion bodies contain gamma-globulins not present in normal nuclei<sup>2</sup>. However, to our knowledge, the histological localization of gamma globulins with fluorescence-labelled antibodies has been carried out only in smears and not in sections of L. E. cells. As a consequence, it is not clear whether the demonstrated gamma-globulins diffusely permeated the inclusion bodies or simply coated them. For the same reason, it is difficult directly to correlate the results obtained with histochemical and immunological methods. In our investigations on the composition of inclusion bodies, it seemed appropriate, therefore, to attempt a more critical localization of gamma-globulin on sections rather than on smears of L. E. cells.

The capillary test developed in our laboratory<sup>3</sup> has permitted us to obtain cell blocks of buffy coat which contained large numbers of L. E. cells and could be readily sectioned. The localization of gamma-globulin in the

sections was accomplished with the help of labelled sera by means of autoradiography, fluorescence microscopy and electron microscopy.

**Autoradiography.** The globulins of L. E. sera were labelled with iodine-125 as recommended by Fitch, Winebright and Harper<sup>4</sup> and according to the technique of Bale *et al.*<sup>5</sup> with the modification that all rinses were carried out with normal human serum rather than with buffered saline. This modification was introduced in order to minimize the use of buffered saline, since the latter was found to interfere with the production of satisfactory L. E. cell preparations. The specific activity of the labelled globulins was 5  $\mu\text{Ci}/\text{mg}$  of protein contained in a 0.3 ml. volume. The blood of a healthy donor was collected in heparinized capillary tubes. After centrifugation, the plasma was replaced carefully with the labelled globulins. A syringe was inserted to mix the white cells and the labelled globulins thoroughly. The capillary tubes were then incubated at 37° C for 30 min and centrifuged again. The resulting white cell pellets were removed, washed, and frozen in a cryostat after infiltration with an embedding compound (O.C.T. for temperature zone 0° C to -15° C, Lab-Tek, Westmont, Illinois, U.S.A.). Frozen sections about 4  $\mu$  thick were mounted on microscopic slides, allowed to dry at room temperature and fixed in 95 per cent ethanol for 5 min. Sections were then coated in the dark room with Ilford K-5 nuclear research emulsion in gel form diluted with an equal volume of water. The slides were sealed in a dry, light-tight box and

Fig. 1. Autoradiograph of sectioned L. E. cells produced with  $^{125}\text{I}$ -labelled globulin of L. E. serum. Note the concentration of grains over the inclusion bodies. Sixteen days' exposure. ( $\times 8,700$ )

kept at  $4^\circ\text{C}$  for one to three weeks. Sensitized silver grains were developed with Kodak D-19 and sections were stained with Wright's stain<sup>4</sup>.

After 7 days' exposure, the number of grains produced by  $^{125}\text{I}$ -labelled globulins was found to be greater over the inclusion bodies of L. E. cells than in the background. The proportion of inclusion bodies with high grain counts increased with the exposure time. After 3 weeks' exposure, more than 80 per cent of the inclusion bodies showed higher numbers of grains than the background. At this time, some inclusion bodies were overlaid by more than 40 grains, while only scattered grains were found in the background. A representative autoradiograph of sectioned L. E. cells after 16 days' exposure is shown in Fig. 1. Increased numbers of grains were also seen over free haematoxylin bodies but rarely over unaltered leukocytes.

**Immunofluorescence.** The direct method using fluorescein-labelled globulins of L. E. sera was found unsatisfactory because only a few L. E. cells were produced by such globulins. The indirect method was therefore applied, by which L. E. cells were produced with unlabelled L. E. sera and afterwards exposed to labelled anti-human gamma-globulin globulins. The labelled globulins had been absorbed with dry mouse liver powder before use. Pellets of leukocytes containing L. E. cells were washed repeatedly with normal rabbit serum to remove unbound L. E. serum. Frozen sections of the pellets were fixed in 95 per cent ethanol for 5 min and incubated with normal rabbit serum to block non-

specific binding sites and then with fluorescein-labelled rabbit anti-human gamma-globulin globulins. Each incubation was carried out at room temperature for 30 min. After washing with buffered saline, the sections were covered with buffered glycerol, and examined under a fluorescence microscope. In order to examine the morphological details of the structures exhibiting specific fluorescence, the same preparations were afterwards stained with Wright's stain.

Inclusion bodies of L. E. cells and free haematoxylin bodies showed specific green fluorescence. In contrast, the leukocytic nuclei of the same L. E. cells and of other leukocytes were devoid of any fluorescence. The specific fluorescence of the inclusion bodies had a homogeneous appearance (Fig. 2, A and B) which correlated well with the homogeneous character of the same bodies as seen with Wright's stain (Fig. 2 C). Pre-treatment of control preparations with unlabelled rabbit anti-human globulin serum blocked the specific fluorescence completely.

**Immuno-electron microscopy.** Globulins of L. E. sera and rabbit anti-human gamma-globulin globulins were labelled with ferritin by means of *m*-xylylene diisocyanate according to the method of Singer and Schick<sup>5</sup>. Labelled globulins of L. E. sera gave unsatisfactory L. E. preparations and could not be used for the purposes of this investigation. On the other hand, recovery of antibody activity in rabbit anti-human gamma-globulin globulins was excellent following their conjugation with ferritin by the same technique. An indirect method was therefore applied as in the case of the immunofluorescence. Pellets of L. E. cells were first prepared with unlabelled sera by the capillary method, washed thoroughly with normal rabbit serum, and fixed for 15 min in 3 per cent buffered formalin, pH 7.4. After rinsing with the same buffer, they were incubated at room temperature with ferritin-conjugated rabbit anti-human gamma-globulin globulins for 60 min. After repeated washings, they were fixed in osmium tetroxide and embedded in 'Epon-812'. Ultrathin sections were examined both before and after staining with uranyl acetate or lead hydroxide in order not to confuse ferritin particles with precipitates of the metallic stains.

A survey view of an L. E. cell from a stained section is illustrated in Fig. 3A. Inclusion bodies appeared homogeneous at low magnification and were always surrounded by a single membrane. The latter could be demonstrated to consist of the invaginated plasma membrane of phagocytizing cells and not of a nuclear membrane of the altered phagocytized nuclei. These and other fine structural characteristics of L. E. cells will be reported in detail elsewhere. Fig. 3B illustrates a field from the same inclusion shown in Fig. 3A before staining. Electron-dense ferritin particles appear irregularly scattered throughout the inclusion body. A detailed count of

ferritin particles was made in several inclusion bodies. Twenty to fifty particles per square micron of section surface were found in sections of an estimated thickness of 800–1000 Å. There were no ferritin particles in the intact nuclei of phagocytizing cells or in the platelets and intact lymphocytes usually present in the same preparations. Occasional particles, however, were attached to the plasma membranes of phagocytizing cells.

The three techniques used in this investigation are complementary, as they permit, by different means, the detection and precise localization of gamma globulin in cells and tissues. They gave uniform and consistent results which are believed reliably to demonstrate the presence of gamma globulin within the inclusion bodies of L. E. cells. While the indirect methods using anti-globulin

antibodies in conjunction with immunofluorescence and immuno-electron microscopy gave strong indication to this effect, more direct evidence was provided by autoradiography in which the labelled globulin of L. E. serum

itself could be used. Since physicochemical differences between L. E. factor and 7-S gamma globulin have not yet been demonstrated, it would seem reasonable to assume that gamma globulin within inclusion bodies consists, at least in part, of the L. E. factor.

This work was supported in part by grant AI-05179 from the National Institute of Allergy and Infectious Diseases, U.S. Public Health Service, and by the Hematology Research Foundation, Chicago.

## CHEMI-LUMINESCENCE AND CHEMI-ELECTRON EMISSION FROM ALKALI AZIDES

By G. D. SINGER and DR. H. J. MUELLER

Basic Research Laboratory, U.S. Army Engineer Research and Development Laboratory, Fort Belvoir, Virginia

At elevated temperatures, Audubert *et al.*<sup>1-3</sup> observed a faint emission of ultra-violet light from various azides by means of a photosensitive Geiger-Müller counter. They ascribed the emission to the thermal decomposition of the specimens and assumed that the intensity of the radiation was a direct measure of the rate of decomposition. Thus they were able to calculate activation energies for the decomposition process from an Arrhenius plot. For the different azides similar activation energies were found and the spectral characteristics of the emissions were practically the same; this was taken as an indication that the same excited species was involved in all cases. Audubert *et al.* concluded, in particular, that the luminescence was due to excited nitrogen and made tentative designations of observed bands to electronic states of molecular nitrogen<sup>4,5</sup>. Recently, a somewhat different designation of these bands has been given by R. W. Nicholls<sup>6</sup>.

It was suggested by Audubert and Mattler<sup>4</sup> that the influence of metal nuclei formed during decomposition is to decrease the intensity of luminescence, the energy of the activated molecule being used to detach an electron rather than to produce photons. Thus, chemi-electron emission might be expected as a result of the reaction. In a recent investigation of the thermo-luminescence of ultra-violet-irradiated alkali azides<sup>7</sup> we observed the simultaneous occurrence of a stimulated electron emission which we associated with the decomposition of the azide. The present investigation was undertaken in order to check this assumption as well as to investigate the feasibility of examining quantitatively the decomposition kinetics of azides by means of chemi-electron emission and chemi-luminescence.

In our experiments the chemi-luminescence of the azides was measured by a photomultiplier with maximum sensitivity in the near ultra-violet. The spectral response of the system was determined by the cut-off of the quartz window of the sample chamber. The limit of detection was of the order of  $10^3$  photons/sec. Electron emission was detected by replacing the photomultiplier arrangement by an open Geiger counter which was insensitive to light, including the near ultra-violet. The sample was shielded from the electric field of the counter by a wire grid which was kept at the potential of the counter

cathode. With this arrangement we could distinguish a few electrons/sec. Some error was introduced by poisoning the counter with decomposition products as the experiment progressed. The sample was mounted on a flat slide of 'Pyrex' glass which could be heated by means of an electric heater.

In accordance with the work of Audubert *et al.*, an emission of ultra-violet light was observed that increased exponentially with temperature. It was found that the presence of a gas atmosphere enhanced the luminescence, although the nature of the gas used (argon, air, carbon dioxide, methane) had little apparent effect. We observed, however, that there was always an optimum pressure (varying from 10 to 100 torr) at which to obtain maximum light emission; in vacuum or under atmospheric pressure the luminescence approached the lower limit of detection. Slowly flowing argon at a pressure of 40 torr was used in most of our measurements in order to achieve a good luminescence yield.

In the experiments the temperature of the sample was raised or lowered at a rate of about 10 deg/min, while the intensity of the light or electron emission was measured as a function of temperature. Assuming that the intensity  $I$  of the emission is proportional to the rate of decomposition  $dc/dt$  and that the amount of the specimen decomposed during the experiment is negligible, the differential equation for the kinetics of the reaction may be written as:

$$I = -\frac{dc}{dt} \approx \text{constant} \cdot \exp(-E/RT)$$

and the energy of activation  $E$  can be readily computed from the slope of an Arrhenius plot. Fig. 1 shows such a plot for the luminescence of  $\text{KN}_3$ ; in Table 1 the average values of  $E$  calculated from our measurements are given for various azides. The spectral distribution of the luminescence was qualitatively determined by means of sharp cut-off filters since the low intensity of the light emission did not permit the use of a spectrometer. More than 90 per cent of the ultra-violet emission was found to lie between 240 and 260 m $\mu$ . There was also luminescence in the visible range, mainly around 560 m $\mu$ , as well as some emission in the infra-red.

Fig. 1. Arrhenius plot for  $\text{KN}_3$ . O, Ultra-violet emission; x, electron emission

At elevated temperatures, electron emission was found for all the azides both in the solid and liquid state. That the emission is entirely made up of negative particles was verified by an electric potential between the sample holder and the Geiger counter; when the sample holder was made negative a small voltage caused an increase in counting rate, while a reverse voltage reduced the counting rate to zero. Fig. 2 shows the electron emission of  $\text{KN}_3$  as a function of decreasing temperature. Although the temperature ranged both below and above the melting-point of the specimen, there was within the experimental errors no change in the exponential slope of the curves when passing from the liquid to the solid phase. At the fusion temperature, however, we frequently noted a peak of the electron emission as seen in Fig. 2. This increase in electron emission that accompanies the solidification of the molten azide is due to the under-cooling of the melt and subsequent sudden release of the heat of crystallization. The tendency of alkali azide melts for under-cooling is also known from calorimetric measurements<sup>8</sup>.

Although the individual luminescence or electron emission curves could be fitted very well to Arrhenius plots, the energies of activation calculated from such plots showed considerable variations. Average activation energies of about 35–42 kcal/mole were found for most of the processes. They are in the same range as the energies observed by Audubert<sup>8</sup> and agree with values of 36 kcal and 41.5 kcal found by others<sup>9,10</sup> for the decomposition of  $\text{KN}_3$  in the presence of potassium vapour.

The ultra-violet emission from  $\text{NaN}_3$  was dependent on the pre-treatment of the sample; initial runs on  $\text{NaN}_3$  sometimes produced activation energies as high as 75 kcal/mole. Energies of this magnitude were also found for the other azides when the runs were carried out in vacuum, or for initial electron emission runs of  $\text{RbN}_3$  and  $\text{CaN}_3$ . In all these cases, however, the energy values showed such a large spread that computation of an average value was not considered to be meaningful, and therefore such values were not included in Table 1. In contrast to the work of Audubert, we did not observe different energies of activation for  $\text{NaN}_3$  above and below 365° C.

From isothermal experiments the order of the decomposition reaction was found to be zero for both lumin-

Table 1. ACTIVATION ENERGIES FOR THE DECOMPOSITION OF ALKALI AZIDES

	(kcal/mole)		
	From luminescence	From electron emission Solid	Melt
$\text{KN}_3$	$41.7 \pm 5.2$	$35.1 \pm 6.3$	$41.5 \pm 6.3$
$\text{RbN}_3$	$39.8 \pm 3.7$	$43.5 \pm 6.1$	$40.5 \pm 3.9$
$\text{CaN}_3$	$41.0 \pm 3.6$	$43.5 \pm 6.5$	$43.6 \pm 7.9$
$\text{NaN}_3$	$35.2 \pm 4.8$	$36.8 \pm 7.1$	

escence and electron emission. This result is in accordance with recent measurements of the nitrogen evolution during the isothermal decomposition of various alkali azides<sup>11</sup>.

The thermal decomposition of metal azides is known to proceed according to the overall equation:  $2\text{MAN}_3 \rightarrow 3\text{N}_2 + 2\text{Me}$ . The details of the reaction are not fully understood yet. The initial step, however, must be the detachment of an electron from the  $\text{N}_3^-$ , either in form of an exciton or by complete ionization. The fact that, so far, it has not been possible to find free  $\text{N}_3$  radicals by spin-resonance techniques during the decomposition of inorganic azides suggests the following two reactions in which free azide radicals are not involved:

the excess electrons usually being captured by metal ions or specks; or in the presence of metal nuclei:

followed by:

or more likely:

From theoretical considerations one should expect for process (1) an energy of activation of about 70–80 kcal/mole<sup>12</sup>. The experimentally observed activation energies with values as high as 75 kcal/mole indicate that reaction

Fig. 2. Electron emission of  $\text{KN}_3$  as a function of decreasing temperature

(1) dominates in the early stage of decomposition, or in vacuum where the metal formed during the decomposition may escape by evaporation. With progressing decomposition the metal produced by the reaction begins to nucleate and the interface reaction (2) with an activation energy of about 35–42 kcal/mole becomes predominant. We consider the simultaneous occurrence of two decomposition reactions which proceed with different  $E$  to be the main reason for the comparatively large fluctuations of the  $E$  values computed from the Arrhenius plots. Although usually one of the competing reactions is dominant and, therefore, the intensity versus temperature curves can be quite satisfactorily fitted to Arrhenius plots, their slopes may differ in identical experiments depending on the contribution of each reaction. Thus, the experimentally determined energies of activation are essentially composite values partly depending on parameters such as initial concentration of metal nuclei, size of interface area, presence of surface impurities, etc. These energies are meaningful, however, in that they represent approximations of the true energies of activation. The limited reproducibility of decomposition experiments with azides under identical experimental conditions is by no means typical for luminescence or electron emission measurements, but has also been experienced when using the nitrogen evolution technique. It probably accounts for the different  $E$  values frequently reported in the literature for the decomposition of azides.

From the thermochemical values given in the literature<sup>13</sup> and from the known energies of activation, the maximum energies made available for excitation by processes (1), (2a) and (2b) were estimated to be 139, 225 and 147 kcal/mole, respectively. If given to a single  $N_2$ , these energies are sufficient to lead to the emission of the observed ultra-violet chemi-luminescence. Nicholls<sup>4</sup> has suggested that the emission in the ultra-violet is identical with the Vegard–Kaplan bands of  $N_2$ , which may be considered to arise from the recombination of atomic N in the  $4S$  state to  $N_2$  in the  $1\Sigma$  state<sup>14</sup>. Process (2) could lead to a single N atom excited with the activation energy of the reaction. This energy, however, is not sufficient to account for the emission observed at 560 m $\mu$ , which may be chiefly due to traces of excited oxygen<sup>15</sup>.

The fact that the energy of activation computed from the electron emission is practically the same as that obtained from luminescence measurements or by observing the nitrogen evolution suggests that the free electrons are an immediate product of the decomposition process, rather than exoelectrons or photoelectrons. The decomposition was found to be a reaction of zero order, indicating a process proceeding at an interface, such as the surface proper of the sample or the interface between the azide and the metal nuclei. This view is supported by the consideration that, in contrast to luminescence, free electrons can be detected only if they are released in the

surface region, but the same course of reaction was observed regardless of whether electron emission or light emission was monitored. It may be assumed, therefore, that reaction (1) occurs only on the surface. This is in accordance with the opinion held by other investigators that the decomposition in the azide matrix is unlikely to occur unless there are metal nuclei present. As to reaction (2), it cannot be decided on the basis of our experiments whether the catalytically active nuclei are homogeneously distributed throughout the volume of the sample or concentrated at the surface only. In both cases a zero-order reaction is to be expected. The observation, however, that the Arrhenius plot shows no substantial change in the slope when passing from the liquid to the solid phase indicates that there is no difference in the catalytic reaction in the two phases. It also shows that reaction (2) is largely independent of specific solid-state defects as well as of the crystalline structure of the solid.

Audubert and Mattler proposed a mechanism, according to which the luminescence is quenched by resonance induction involving metal nuclei, to explain their observation that the luminescence was enhanced by a moving gas. Our observation was that the pressure of the gas rather than the circulation was of primary importance, and we propose the following explanation for the existence of an optimum pressure. The increase of luminescence with increasing pressure can be understood as a pressure dependency of the decomposition reaction itself. The formation of metal nuclei is governed by two competing processes, that is, formation by the decomposition and simultaneous evaporation of the nuclei. An external pressure will favour the growth of nuclei by reducing the evaporation rate and thus eventually cause an increase of the reaction rate. However, with increasing pressure the probability for quenching of the luminescence of the excited  $N_2^*$  and  $N^*$  by collisions of the second kind, either with metal atoms or molecules of the surrounding gas, will also increase, causing a decrease of the luminescence yield. Superposition of both effects results in the occurrence of an optimum pressure for the luminescence.

We thank Dr. Z. V. Harvalik, director of the Basic Research Laboratory, and Mr. R. C. McMillan for their advice

## RADAR INVESTIGATIONS OF WORLD-WIDE IONOSPHERIC DISTURBANCES ASSOCIATED WITH SATELLITES

By PROF. MARTTI TIURI

Institute of Technology, Helsinki, Finland

**R**ESULTS of high-frequency and very-high-frequency radar investigations are described, which seem to indicate that ionospheric disturbances associated with a large satellite can be detected by a north-looking radar, situated close to the northern auroral zone, when the satellite is approaching the magnetic latitude of the radar either in the northern or in the southern hemisphere. The reflexions from the disturbances have no Doppler-shift and

their occurrence is dependent on the local time and the heading of the satellite. These phenomena are detected during magnetic disturbances only and are thought to be correlated with magnetic shell enhancements of the electron density in the upper ionosphere. When the satellite passes such an enhancement it may trigger a disturbance which can be detected at places close to the corresponding magnetic shell.

Fig. 1. Orbit of Echo 1

Satellite associated ionospheric disturbances occurring close to the satellites have been searched with positive<sup>1,2</sup> and negative results<sup>3</sup>. In the pulse radar investigation in Ohio in winter 1961-62 (ref. 2) the large radiotelescope antenna was used to achieve high sensitivity. Only relatively strong echo signals were taken into account in the analysis. It was found that these signals, which did not have any Doppler shift, tended to occur at times when the largest existing satellite *Echo 1* was close to the north-looking antenna beam. Disturbances seemed to occur in the antenna beam especially at the time when *Echo 1* was near to the most northerly point of its orbit about 100-500 km westward from the longitude of the radar. This seems to indicate that satellite-induced disturbances can travel rapidly eastward along the line of magnetic latitude.

**Investigations using 17 Mc/s CW radar.** In spring 1964 an investigation was started in Finland to find out how far away from the satellite it would be possible to detect satellite-correlated ionospheric disturbances. Assuming that disturbances travel to the east along the lines of magnetic latitude, disturbances associated with *Echo 1* can be detected in Finland only when *Echo 1* is near to the most northerly point of its orbit over the United States. The corresponding equator-crossing longitudes of the orbits are about 120°-230° W (Fig. 1). Elsewhere the orbit is to the south from the magnetic latitude of Finland. The orbit of the largest satellite *Echo 2* reaches the latitude 81.5° N and hence crosses the magnetic latitude of Finland twice during each revolution.

The transmitter power of the CW radar was 1 kW at 17 Mc/s. The antenna was a quarter-wave vertical mast with director pointing to the north. The receiving antenna consisted of two horizontal north-looking three-element yagis in parallel. The receiver bandwidth was about 1 kc/s. Owing to interference observations were

possible only during night time, and were performed during two months beginning February 22, 1964. In the analysis all signals lasting over 25 sec and less than 2.5 min and having a receiving power over -115 dBm were taken into account. Almost two hundred such signals were obtained, that is, on the average three signals a night. The lower limit of 25 sec was chosen to leave out of the analysis most of the meteor signals.

**Echo 1 results.** Fig. 2 shows the histogram of 65 signals obtained during the time *Echo 1* was in the orbits 120°-230° W. The number of signals per 10-min intervals is

Fig. 2. Histogram of the signals received during the orbits 120°-230° W of *Echo 1*, February-April, 1964. 17-Mc/s CW radar in Finland

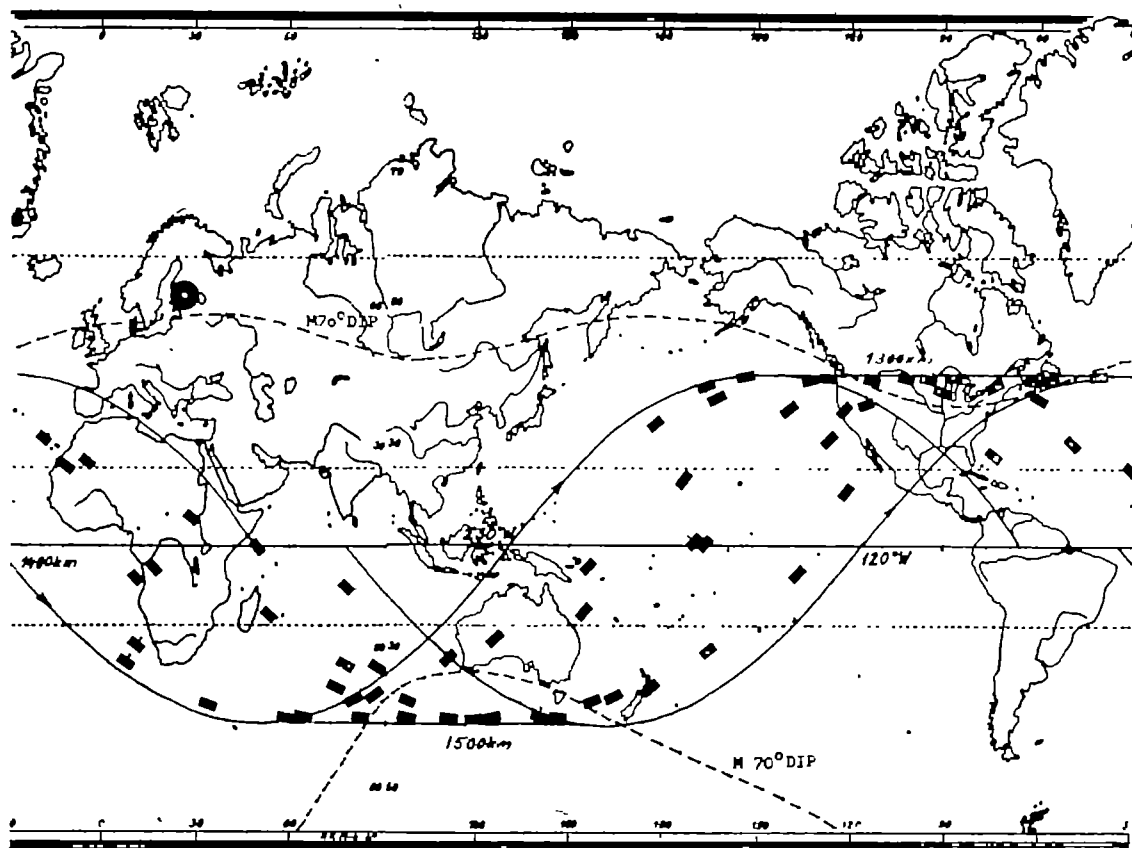

Fig. 3. Positions of *Echo 1* when radar reflexions were received in Finland, February–April, 1964, 17 Mc/s

shown with respect to the south–north equator-crossing time (ECT) of *Echo 1*. Fig. 3 shows the map of the positions of *Echo 1* at the times when signals were received. Lines of constant magnetic dip angle of  $70^\circ$  are also shown. They correspond approximately magnetic co-ordinate value  $L=3$ . The height of the satellite varied from 1,200 to 1,600 km. The histogram has two peaks about 30 min before ECT and about 25 min after it. The positions of *Echo 1* tend to concentrate close to the most northern and most southern points of the orbit. The most southern points happen also to be close to the southern magnetic latitude corresponding to that of the radar station. This unexpected result seems to indicate that satellite-associated disturbances are able to travel from the southern to the northern hemisphere with the same magnetic dip angle. The velocity of travel must be high in comparison with

the velocity of the satellite. In Fig. 4 only signals lasting more than 40 sec are shown. The peak at  $-30$  min has completely disappeared. This indicates that disturbances from the southern hemisphere are weaker. Satellite-related ionization effects between hemispheres have also been suggested by Kraus<sup>4</sup>.

Eighty-three signals were received during the time *Echo 1* was on the orbits  $230^\circ$ – $350^\circ$  W. Fig. 5 shows the histogram of these signals with respect to the ECT of *Echo 1*. As expected it resembles a more uniform distribution.

Fig. 4. Histogram of signals received during the orbits  $120^\circ$ – $150^\circ$  W of *Echo 1* and lasting more than 40 sec. 17-Mc/s OW radar in Finland

Fig. 5. Histogram of the signals received during the orbits  $230^\circ$ – $350^\circ$  W of *Echo 1*. February–April, 1964. 17 Mc/s OW radar in Finland

**Echo 2 results.** *Echo 2* traversed approximately in orbits  $100^{\circ}$ – $200^{\circ}$  W when the signals in Fig. 2 and 3 were obtained. The histogram of all the signals during the orbits  $100^{\circ}$ – $100^{\circ}$  W with respect to the ECT of *Echo 2* is shown in Fig. 6. No prominent peaks are present. *Echo 2* passed the radar station due south at midnight and just after midnight.

The orbit of *Echo 2* is approximately tangential to the southern magnetic latitude corresponding to that of Finland when the satellite moves in the south from Africa. The number of signals received during these orbits (equator-crossing longitudes  $200^{\circ}$ – $280^{\circ}$  W) was 106 including most of the signals shown in Fig. 5 and only a few from Fig. 2. Fig. 7 represents the histogram of these signals with respect to ECT of *Echo 2* and Fig. 8 shows a part of the map of the positions of *Echo 2* when signals were received. The height of *Echo 2* varied from 1,000 to 1,300 km. There is a distinct peak at 25–30 min before ECT when *Echo 2* has been directly to the south from Finland. This

Fig. 6. Histogram of signals received during the orbits  $100^{\circ}$ – $200^{\circ}$  W of *Echo 2*. February–April, 1964. 17-Mc/s OW radar in Finland

Fig. 7. Histogram of signals received during the orbits  $200^{\circ}$ – $280^{\circ}$  W of *Echo 2*. 17-Mc/s OW radar in Finland

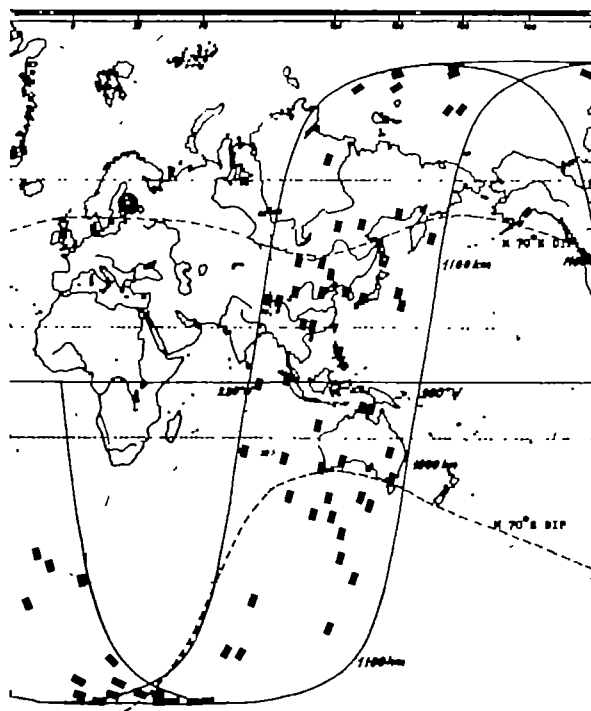

Fig. 8. Positions of *Echo 2* when radar reflections were received in Finland February–April, 1964. 17-Mc/s OW radar

seems to confirm the assumption that satellite-associated disturbances can travel from the south to the corresponding northern magnetic latitude.

**Sputnik 3 results.** During the winter 1959–60 *Sputnik 3* was the only large satellite. 100-Mc/s CW radar observations of satellite-associated ionospheric disturbances were made in Finland\*. The geomagnetic geometry of orbits  $30^{\circ}$ – $90^{\circ}$  W of *Sputnik 3* was similar to the orbits  $120^{\circ}$ – $230^{\circ}$  W of *Echo 1* except that *Sputnik 3* passed the radar station almost at the most northerly point of the orbit. The analysis of observations shows characteristics similar to Fig. 2–4 of *Echo 1*.

**Conclusions: related phenomena.** The results obtained suggest that large satellites when orbiting at heights of 300–1,500 km close to the auroral zones ( $L$  co-ordinate values between 3 and 6) are able to induce ionospheric disturbances which can be detected at the corresponding magnetic latitudes on the northern and on the southern hemisphere. These phenomena imply a moderate magnetic storm and are also dependent on the local time. Favourable times for receiving signals are from about 4 to 10 a.m. and from 4 to 10 p.m. The heading of the satellite is also important.

The satellite *Ariel* has measured electron density variations in the heights of 400–1,200 km (ref. 6). During magnetically disturbed periods sharp electron density enhancements were observed with a structure resembling magnetic shells ( $L$  values 3–8 for moderate storms). It is supposed that a large satellite, when grazing or crossing such a shell, can trigger a disturbance detectable by high-frequency radar in the vicinity of the corresponding northern and southern magnetic latitudes.

Very-low-frequency noise bands observed by the *Alouette 1* satellite between  $L$  values 2.5 and 4 (ref. 7) can be related phenomena. There are also similarities between satellite-related ionization effects and the way the satellite *Io* controls the decametric radiation from Jupiter\*. Decametric radiation from Jupiter is obtained when *Io* is near local sunrise to sunset and at the same time near magnetospheric shells with the highest  $L$ -values (about

6.5). These similar circumstances suggest that the satellite ionization phenomenon and the decametric radiation from Jupiter may be different manifestations of the same mechanism in which a satellite interacts with an electron shell in the magnetosphere<sup>5</sup>.

## MATTER CREATION BY GRAVITATIONAL WAVES

By M. CLUTTON BROCK

Department of Mathematics, Northampton College of Advanced Technology,  
St. John Street, London, E.C.1

THE idea of a steady-state universe has an immediate aesthetic appeal which is marred by the reflexion that the spontaneous creation of matter appears to violate the most fundamental conservation law known to science. It is true that the quantities involved are so minute as to be undetectable by direct observation, but this does not lessen the surprise. For the conservation of energy and momentum is equivalent to the invariance of time and space under translation, and a minute violation of a symmetry principle is just as surprising as a large violation.

If a particle is created in our locality, we should look for some asymmetry in the neighbouring space time to account for the apparent non-conservation of energy and momentum. I suggest that we might find such an asymmetry in the form of a rapid fluctuation of the curvature of space time in the neighbourhood of the created particle. We should identify this rapid fluctuation with gravitational radiation, and we should say that the absorption of gravitational radiation had resulted in the emission (or creation) of matter.

While there can at present be no direct experimental evidence for the creation of matter by the action of gravitational radiation, there is at least some indication from orthodox relativity theory that such a mechanism should be possible. Wheeler<sup>1</sup>, in discussing the superdense star, comes to the conclusion that pressures enormously greater than those in nuclear matter must be able to convert nucleons into free radiation. Now, if this is so, the reverse transformation should be possible—free gravitational radiation should be convertible into nucleons. McCree<sup>2</sup> has discussed the fall of a particle from infinity on to the Schwarzschild singularity of a large body. If the particle is brought to rest, and the kinetic energy transformed into radiation, then there is no increase in the proper mass of the body, and the energy of the radiation (observed at infinity) is just equal to the rest mass of the particle. Again, the reverse transformation should be possible: gravitational radiation should be able to detach a particle from the Schwarzschild singularity of a body, and impart to the particle sufficient kinetic energy to escape. The proper mass of the body will be unchanged, and the energy supplied by the radiation will be equal to the rest mass of the particle.

The properties of gravitational radiation are difficult to observe experimentally and are theoretically obscure. Let us assume that gravitational radiation is quantized into gravitons, each of which has energy given by the Planck relation  $E = h\nu$ . Now, most known gravitational processes take place at very low frequencies, whereas the production of nucleons would require high-energy gravitons with frequencies of the order of  $10^{24}$  c/s. Where can such high frequencies be found? I suggest that the answer lies in the advanced wave from distant sources.

The Wheeler-Feynman<sup>3</sup> formulation of electrodynamics postulates a time-symmetric solution, with an advanced field as well as a retarded field. The advanced field is converted into a retarded field plus radiation reaction by the action of a distant absorber. Presumably, a similar formulation may be made for gravitation, with this difference—that the absorption of gravitational radiation is extremely low. The advanced wave, instead of being converted into radiation reaction, will be propagated to the remotest parts of the universe with negligible attenuation.

Gravitational waves, like light waves, will be affected by the Doppler shift due to the galactic recession. Whereas the retarded wave is shifted to lower frequencies, the advanced wave is shifted to higher frequencies and to higher energies.

We can derive the Doppler shift most easily by subjecting the momentum 4-vector of the graviton to a Lorentz transformation. Considering for simplicity the case of one space dimension, we can write the momentum of the retarded graviton as  $\{p, +ip\}$ , and that of the advanced graviton, which travels backwards in time (so that  $dt/ds$  is negative), as  $\{p, -ip\}$ . If the observer is receding from the source with velocity  $v = \beta c$ , then the observed momentum of the retarded graviton will be

$$\begin{bmatrix} \gamma & +i\beta\gamma \\ -i\beta\gamma & \gamma \end{bmatrix} \begin{bmatrix} p \\ +ip \end{bmatrix} = \gamma(1-\beta) \begin{bmatrix} p \\ +ip \end{bmatrix}$$

while that of the advanced graviton will be :

$$\begin{bmatrix} \gamma & +i\beta\gamma \\ -i\beta\gamma & \gamma \end{bmatrix} \begin{bmatrix} p \\ -ip \end{bmatrix} = \gamma(1+\beta) \begin{bmatrix} p \\ -ip \end{bmatrix}$$

Here  $\gamma = (1-\beta^2)^{-1/2}$  and so the momentum, and hence the frequency, of the advanced graviton is increased by a factor of:

$$\gamma(1+\beta) = \{(1+\beta)/(1-\beta)\}^{1/2}$$

The overall effect can be seen from a space time diagram, as in Fig. 1. Pulses emitted by the source are received at longer intervals at the retarded wave, and at shorter intervals at the advanced wave.
